Chapter 1 - Introduction and Literature review

Definition and Epidemiology

A surgical complication is described as any ‘undesirable, unintended and direct result of an operation affecting the patient, which would not have occurred had the operation gone as well as could reasonably be hoped’. A more inclusive definition is ‘any deviation from the ideal postoperative course that is not inherent in the procedure and does not comprise a failure to cure’. Surgical complication in this study includes both adverse events and negligence cases as defined by Brennan et al. An adverse event injury is one caused by medical management (rather than the underlying disease), and negligence refers to care that falls below the standard expected of surgeons in their community.

Surgical complications are common and most of them are preventable. Andrew et al’s prospective observational study of 1997, carried out in three large teaching hospitals in the United States of America, showed that 17.7% of inhospital patients experienced at least one serious adverse event. Wanzel et al showed an incidence of 39% of surgical complications in a prospective study of 192 patients carried out in Wellesly Central Hospital in Canada in 2000, of which 18% were due to error. De Vries et al’s systematic review revealed that 1 in 150 patients admitted in hospital...
have an adverse event, and that 2/3 of in-hospital events are associated with surgical care. Adverse events have been estimated to affect between 3% and 16% of all hospitalized patients, and more than half of such events are known to be preventable\textsuperscript{3,8,9,10}. Several studies have shown that between 53% and 70% of surgical errors occur outside theatre before and after surgery\textsuperscript{11,12,13,14}. The introduction of a safety checklist is necessary in order to decrease these errors.

The incidence of surgical complications differs between developed and developing countries. The incidence of major complications in developed countries is quoted as between 3% and 22% of inpatient surgical procedures and deaths due to complications fall between 0.4% and 0.8\%\textsuperscript{19,20}. Nearly half of these adverse outcomes were determined to be preventable\textsuperscript{19, 20}. In developing countries, deaths rates associated with major surgery were cited as between 5% and 10\%\textsuperscript{21,23}.

**Classification**

There is currently no universally accepted and widely used classification for surgical complications, but the Clavien-Dindo grading system which was introduced in 1992, and subsequently modified in 2004, is the most commonly used (Table 1)\textsuperscript{17,18}. The difficulty with this classification system is underreporting. The unavailability of a universally accepted classification system makes it difficult to obtain data in a standardized manner, and for
different centres to compare their outcome. In our study we did not use any classification system but compared like for like of complications before and after implementation of the surgical checklist.

**Table 1: Clavien-Dindo grading system for the classification of surgical complications**

WHO Checklist

The main goal of the WHO guidelines for safe surgery (2009) was to improve patient safety policy and practice in every country in the world irrespective of the economic status, through development of an effective checklist that could be modified for an individual country\textsuperscript{16}. The main objectives were to ensure that:

1) The team will operate on the correct patient at the correct site.

2) The team will use methods known to prevent harm from administration of anaesthetics, while protecting the patient from pain.

3) The team will recognize and effectively prepare for life threatening loss of airway or respiratory function.

4) The team will recognize and effectively prepare for risk of high blood loss.

5) The team will avoid inducing an allergic or adverse drug reaction for which the patient is known to be at significant risk.

6) The team will consistently use methods known to minimize the risk for surgical site infection.

7) The team will prevent inadvertent retention of instruments and sponges in surgical wounds.

8) The team will secure and accurately identify all surgical specimens.
(9) The team will effectively communicate and exchange critical information for the safe conduct of the operation.

(10) Hospitals and public health systems will establish routine surveillance of surgical capacity, volume and results.

A modified multidisciplinary World Health Organization safety checklist was introduced at our institution - Charlotte Maxeke Johannesburg Academic Hospital, Division of Orthopaedics on the 1st March 2011 (appendix 4). Prior to this there was no formal surgical safety checklist. Pre-operative work-up which included, inter alia, checking and acting on blood results, pre-operative optimizing of patients by consulting other relevant medical specialties, limb marking and informed consent was in most instances delegated to the most junior member of the team (intern/ medical officer or junior registrar). With the checklist, at least one of the surgeons checks all of the above and makes sure that the patient is ready before being booked.

The surgical safety checklist list consists of 3 components, namely the pre-operative, intra-operative and immediate post-operative section (appendix 4). The pre-operative section contains 14 items, including the American Society of Anaesthesiologists’ (ASA) rating of patients. Subsequent items on the checklist ensure that an electrocardiogram and chest x-ray are completed and that routine bloods are taken, checked and documented.
The surgical site is marked and most importantly informed consent is documented. Pre-operative planning, including the ordering of implants, is done. This document must be checked by the registrar or the surgeon pre-operatively and any missing information rectified prior to the patient being booked by the team for surgery. Patients found to be unfit for surgery are cancelled immediately and replaced with other patients.

The intra-operative section, as with the original World Health Organization checklist, comprises 20 items divided into 3 parts (before induction, before skin incision and before leaving the theatre). The first section i.e. before induction consists of 7 items to be checked by the scrub sister once the patient is in theatre. This includes confirming the patient’s identity. The marked site of operation is confirmed to be correct and any known allergies are noted. The anaesthetic equipment is also checked including making sure that all surgical sets are available and sterilized. Any discrepancies are identified and rectified before the patient is given any form of anaesthesia. A further check is completed before skin incision by any member of the theatre personnel (scrub sister/ surgeon or anaesthetist). This verifies all the details again, starting with the name of patient, the procedure, consent and implants availability. If any discrepancy is found it is rectified before skin incision. In addition, prior to leaving theatre, the scrub nurse, anaesthetist and the surgeon have to confirm that there were
no problems during the operation (appendix 4 page 3). Any anticipated immediate post-operative complications must be clearly identified, recorded and communicated to ward personnel. This intra-operative section also includes a section of theatre operation notes which details the date, ICD 10 code of procedure, surgeon and assistants, position of patient, duration of operation, tourniquet and theatre time. Lastly the details of the operation (surgical approach, implants used and post-operation instructions) are fully and clearly documented (appendix 4 page 4).

The post-operative section is completed by the orthopaedic registrar involved in the case to check, amongst other things, that the operated limb is perfusing well and that thromboprophylaxis and antibiotics are prescribed where indicated immediately after theatre in the ward (appendix 4 page 2).

The WHO safety checklist was validated by the multicenter World Health Organization “Safe Surgery Saves Lives” program\textsuperscript{12}. This program was carried out at academic and district hospitals in 8 different countries with diverse populations and Gross Domestic Product. These countries included Canada, India, Jordan, New Zealand, Philippines, Tanzania, England and the USA. The study, conducted by Haynes et al\textsuperscript{12} looked at peri-operative patients only and showed a reduction in the rate of major complications from 11.0\% to 7.0\% and also a decrease in mortality from 1.5\% to 0.8\%\textsuperscript{5}. 

Subsequently, *de Vries et al*’s\textsuperscript{11} Surgical Patient Safety System (SURPASS) collaborative study showed similar reduction in complications from 27.3\% to 16.7\% and reduction in mortality from 1.5\% to 0.8\%. This was a comprehensive study in that it included patients who were followed up from admission to discharge (i.e. the entire surgical pathway). The SURPASS study was carried out in the Netherlands and involved academic, tertiary teaching and regional teaching hospitals where the standard of care is very high. The reduction in mortality attributed to a safety checklist was further reinforced by *Neily et al*’s\textsuperscript{16} study which showed a reduction in complications of 18\% in 74 institutions that introduced the safety checklist compared to a 7\% reduction in 34 institutions without a checklist.
Chapter 2: Research Question

Background:

Charlotte Maxeke Johannesburg Academic Hospital is a level 1 trauma centre and one of the two main teaching hospitals of the University of the Witwatersrand catering not only for inner centre of Johannesburg but also for the whole of South Gauteng, neighbouring provinces and countries. In 2010, the division of orthopaedics admitted a total of 2408 patients of which 2255 had operations and 21495 patients were seen in outpatients.

Prior to the introduction of a surgical safety checklist, surgical outcomes in the division of orthopaedics were evaluated by weekly morbidity and mortality meetings chaired by consultants. There was no formal pre-operative checklist. A checklist has now been introduced.

Hypothesis:

The introduction of a surgical safety checklist in our institution will lead to reduction in mortality, morbidity and cancellation.
Aim/Objectives:

The aim of the study was to assess whether there is any difference in health care before and after the introduction of safety checklist in terms of:

1. Mortality rate
2. Morbidity rate
3. Surgical cancellation rate

Secondary Objective:

To establish whether a surgical safety checklist should be implemented in orthopaedic departments of the University of the Witwatersrand.

Significance:

There is currently no published study about surgical safety checklists in South Africa, hence the need for this study in order to assess whether a safety checklist would be effective in our setting. With the ever spiralling costs of health care, reducing complications would help to decrease the cost of health care and save lives.
Chapter 3: Study design and methodology

Study Design

This was a retrospective observational study from stored database hence no consent was needed from patients.

Statistical analysis

We intended to enroll 500 consecutive patients as per Haynes et al’s study. The sample size was calculated to detect a 20% reduction in complications after implementation, with statistical power of 80% and alpha value of 0.05.

Intervention:

Data was collected from the saved orthopaedic department database of weekly morbidity and mortality (MM) reports presented by registrars to the department from the 1st January 2011 to 29th February 2011 (2 months) as the pre-implementation phase. These morbidity and mortality meetings were chaired by senior consultants of the division of orthopaedics. The
data from March 2011 was taken as familiarization month with the checklist. From the 1st April 2011 until 31st May 2011 (2 months) post-implementation morbidity and mortality data was analyzed and compared with the pre-implementation data.

**Inclusion criteria**

All elective patients admitted in all the units of the division (inclusive of emergency admitted patients who were subsequently operated on elective “list”). Prior to implementation, all involved personnel (consultants in orthopaedics and anaesthesia, registrars in departments, nursing staff in the wards and theatre and clerical staff) were familiarized with the checklist using lectures.

**Exclusion criteria**

All emergency patients sent directly for operation from the emergency department. These included polytrauma patients who had been treated using “Damage Control Surgery” principles.
Chapter 4: Results

Data was collected using Microsoft excel and stata version 11.1. Fisher’s exact test was used to compare the difference pre-implementation and post-implementation.

</table>

There was a significant increase in pediatric cancellations post-implementation (7) from pre-implementation period (3) (see table 3). The 3 pre-implementation patient cancellations were due to lack of time (1), gastro-enteritis (1) and general anaesthetic risk (1). Post-implementation cancellations were due to lack of time (3), upper respiratory infection (2) and faulty anaesthetic machine (2). The causes were unavoidable and in both cases beyond the surgeon’s control. Similarly for trauma there was an increase in cancellations from 17 to 19 while in the other specialties there was a decrease in cancellation rates.
Graph 1 shows the causes of mortality in the pre-implementation and post-implementation periods. The mortality rate decreased by 0.42 %, from (8/438) 1.83% to (6/425) 1.41% at pre-implementation period compared to post-implementation period. Statistically there was no difference in the mortality rate between the pre-implementation period and post-implementation period (p<0.789).

Figure 1: Total of pre-implementation and post-implementation avoidable cancellations

There were 25 cancellations before and 33 after implementation (Table 5). Overall there was no difference between the 2 groups. However if one divides them into un-avoidable and avoidable groups, there was 1.57% reduction of avoidable cancellations (10/438) 2.28 % compared to (3/425) 0.71% as shown in figure 1 above.
Only 77% of registrars acknowledged performing pre-operative planning prior to implementation compared to 87.5% post-implementation, as shown in graph 3. This means that 12.5% of our registrars still do not practice pre-operative planning, post-implementation of the checklist, although this was not statistically significant ($p<0.062$). There was also an increase from 50% to 71% of those who have heard of a surgical safety checklist at pre-implementation compared to post-implementation, which was statistically significant ($p<0.004$). Despite the implementation there was an increase of only 2% (77% to 79%) of registrars who thought that the checklist was essential for overall patient care ($p<0.0865$).
The introduction of a surgical safety checklist is associated with reduction of mortality, avoidable morbidity and cancellations. This is consistent with the published literature which indicates that the introduction of a surgical safety checklist was associated with reduction of surgical complications as per the original mandate of the “Safe Surgery Saves Lives” WHO initiative\(^4\),\(^11\),\(^12\).

There was a significant increase in the percentage of registrars who were initially not routinely practicing pre-operative planning from 77% to 87.5% and also of those who have heard of a checklist (50% to 71%) from pre-implementation to post-implementation. This could be explained by the fact that some registrars were not rotating at CMJAH during the study period but the survey included all registrars in the circuit. Despite this there was little difference regarding their opinions as to whether it is essential for overall patient care pre-implementation and post-implementation. Not all registrars in the circuit completed the survey as some would have been at outreach hospitals, attending to emergencies or on leave.

Regarding the total cancellations results, there was no difference between the two study groups but when only avoidable cancellations were
scrutinized there was a 1.6% reduction. One would have expected a decreased overall number of cancellations post implementation but in our case this could be accounted for by intentional overbooking/ having patients on standby in case a surgery is cancelled and another patient may take the booking. Patients were informed that they were on standby and would subsequently be put on the next list if they were not operated on. Unfortunately we did not specify or indicate in our records whether the cancelled patient was a standby patient, therefore this affected our analysis of cancellations. One might argue that patients with cardiac problems should be included in the “unavoidable” section but we included them in the “avoidable” section because these are high risk patients who should be fully worked up by the treating orthopaedic team in conjunction with anaesthetists and cardiologists. This would lead to fewer cancellations and also lower morbidity and mortality. Routinely, other specialists are involved but the high cancellation rate could be explained by the pre-operative workup which is mostly done by junior members of the anesthetic team only to be cancelled by consultants in theatre the next day. To overcome this, back-up cases were added on lists to fully utilize the theatre time.

On comparing our study to the published data, we see that Haynes et al\textsuperscript{12} showed a reduction of 3\% in morbidity while De Vries et al\textsuperscript{11} showed a decrease of 10.6\% compared to a modest 0.8\% decrease in avoidable morbidity in our study. The abovementioned published studies involved all
patients in surgical disciplines including emergency patients where the risk of complications is high. Our study was limited to elective patients and emergency patients who were operated in elective list.

Our study also showed a decrease in mortality rate of 0.42%, which is comparable to the published data of 0.7% (de Vries et al\textsuperscript{11} and Haynes et al\textsuperscript{12}). It is very hard to attribute the reduction of mortality in our studies to our checklist as the documented cases’ cause of death was from unavoidable causes. These were fully discussed in our mortality and morbidity meetings and were found to be unavoidable. For example, all of the mortality cases from respiratory failure were from the spine unit with high cervical spine injuries. Regardless of the checklist the mortality rate from respiratory complications is approaching 100% within a few months of admission.

Compared to published studies our sample size was very small and the study period very short (total of 5 months) inclusive of 1 month for getting acquainted to the surgical safety checklist. We found that the pre-operative and intra-operative sections of the checklist were fully completed compared to the post-operative section as most doctors would revert back to the medical file for documentation rather than the checklist.
The limitations of this study include underreporting of morbidity and cancellation rates by the units of the division of orthopaedics. Also, only in-patient morbidities were recorded. Thus, patients who presented in outpatient with post-operative morbidities were not recorded. In addition, the Hawthorne effect might have played a role with more active documentation and reporting after implementation, as registrars knew their documentation was being closely scrutinized.
Chapter 6: Conclusion and recommendation

Conclusion

The implementation of a surgical safety checklist was associated with a reduction in mortality, avoidable morbidity and cancellation.

Recommendation

Surgical safety checklists should be regarded as a standard practice for all orthopaedic procedures to decrease complications especially in high operation volume and training centers.

Appendix 5

Ward pre-operative checklist: Registrars Survey

1. During your time in orthopaedics have you had the following:
   
<table>
<thead>
<tr>
<th>Yes</th>
<th>No</th>
<th>Preventable</th>
</tr>
</thead>
</table>
   1.1 Patient cancellation
   1.2 Intra-operation surgical errors
   1.3 Recovery room morbidity
   1.4 Immediate ward morbidity
   1.5 Post mortem morbidity

2. Do you routinely do pre-op planning?

3. Have you heard pre-op checklist?

4. In your opinion /experience do you think pre-op checklist would lead to:
   
<table>
<thead>
<tr>
<th>Yes</th>
<th>No</th>
<th>Don't know</th>
</tr>
</thead>
</table>
   4.1 Decrease in cancellation
   4.2 Decrease in surgical errors
   4.3 Decrease in morbidity
   4.4 Decrease in mortality
   4.5 Decrease in workload

5. In your opinion /experience do you think pre-op checklist is essential for overall patient care?
   
<table>
<thead>
<tr>
<th>Yes</th>
<th>No</th>
<th>Don't know</th>
</tr>
</thead>
</table>

6. Should patient be sent to theatre without the checklist been filled?
   
<table>
<thead>
<tr>
<th>Yes</th>
<th>No</th>
</tr>
</thead>
</table>

7. COMMENTS?
