A Retrospective Review of Early Complications in Adult Liver Transplant Recipients at Wits Donald Gordon Medical Centre

Dr Sheetal Chiba

A research report submitted to the University of the Witwatersrand, Johannesburg in fulfilment for the requirements of the Degree of Master of Medicine 2018.
DECLARATION

I, Sheetal Chiba, declare that this research report is my own work, which is being submitted for the degree Master of Medicine (in the submissable format with my protocol and an extended literature review) in the department of Internal Medicine at the University of the Witwatersrand, Johannesburg. It has not been submitted before for any degree or examination at this or any other university.

........................................

20th day of November 2018
ACKNOWLEDGEMENTS

A heartfelt thanks goes to my two supervisors.
Dr GK Schleicher, many thanks for affording me the opportunity of doing this project. Your ongoing guidance, support and time set aside throughout this process, as well as your knowledge has certainly provided a solid foundation from which I could accomplish this project. Your dedication and work ethic has been a true inspiration.
Dr Lowman, for agreeing to be my second supervisor. Your expertise in the field and assistance has allowed me to achieve this goal.
Dr Fabian and Heather Maher for your guidance and assistance to complete this project.
Finally, to my loving husband Sumesh and my family, thank you for your endless support, love and patience throughout this journey.
This project is dedicated to my late mom, Premilla Chiba.
PRESENTATIONS ARISING FROM THIS PROJECT

A Retrospective Review of Early Complications in Adult Liver Transplant Recipients at Wits Donald Gordon Medical Centre
Wits Donald Gordon Medical Centre Research Day 20th October 2017
ABSTRACT

Background
Deceased donor liver transplants (DDLT) are the only type of liver transplants performed in adults at WDGM. Infections, graft dysfunction, biliary, gastro-intestinal tract (GIT), vascular, renal, respiratory and neurological complications are the most common complications in the early post-transplant period and account for most of the early morbidity and mortality.

Objectives
Firstly, to provide a descriptive analysis of all complications occurring in the first thirty days post operatively in adult liver transplant recipients. Secondly, to investigate any association between recipient demographic data (age and gender), ascites, diabetes and MELD score and subsequent complications.

Methods
A retrospective chart review of all adult DDLT recipients for the first thirty days post-transplant was performed at WDGM for the period January 2015 to December 2016. Complications were classified as infectious or non-infectious. Categorical and continuous variables were analyzed. Fischer’s exact test is used to assess the relationship between demographic data and the presence or absence of infectious complications, while independent sample t-test is used for non-infectious complications.

Results
78 DDLT were performed, with 6 mortalities (8%) in the first 30 days post transplantation. The median length of ICU stay was 6 days (range 2-30 days). The median age of transplant recipients was 54 years, with 54% males. In total 24 patients (31%) had infectious complications in the first 30 days. 16 patients (67% of the infectious cohort) had intra-abdominal sepsis. Six patients (25%) had lower respiratory tract infections, 6 (25%) had skin and soft tissue infections and 3 (13%) had urinary tract infections. Of all infectious complications, 7 patients (29% of the infectious cohort) developed bacteraemia. In total 55 patients (71%) had non-infectious complications. The most common was renal complications...
which occurred in 37 patients (67%). 33 patients (60%) had GIT (hepatic, biliary and intestinal), 24 patients (44%) had respiratory, 13 (24%) had neurological, 10 patients (18%) had vascular, 11 patients (20%) had haematological, and 6 patients (11%) had cardiac complications respectively. Thirteen patients (24%) developed tacrolimus toxicity and 2 patients (4%) had other drug reactions. Acute rejection was suspected in 3 patients (5%). There was no significant association between any of the demographic variables (age, gender), ascites, diabetes mellitus, MELD score and the presence or absence of any complications (infectious and/or non-infectious).

Conclusion

This comprehensive report from South Africa documents complications that occurred within 30 days post liver transplantation in adult recipients.

Non-infectious complications occurred more commonly than infectious complications (71% vs. 31%). The most common infectious complication was intra-abdominal sepsis, and the most common non-infectious complication was renal dysfunction. There was no significant association between any of the demographic variables (age, gender), ascites, diabetes mellitus and MELD score and the presence or absence of any complications.

CHAPTER 1: PROTOCOL WITH EXTENDED LITERATURE REVIEW

1.1 Introduction

1963 marks the first human liver transplant. In adults, deceased donor liver transplants (DDLT) are the only type of transplant performed in sub-Saharan Africa, whilst living donor liver transplants (LDLT) are routinely performed worldwide. There are only two adult liver transplant centers in sub-Saharan Africa, Groote Schuur Hospital (GSH) in the Western Cape and Wits Donald Gordon Medical Centre (WDGMC), both in South Africa.

Indications for liver transplantation include acute fulminant liver failure and chronic end stage liver disease (ESLD) due to various causes, which include cirrhosis, biliary disease, vascular pathology and malignancy. Liver transplantation is considered when decompensated cirrhosis or liver failure develops. This is defined by the presence of a major complication of cirrhosis, which includes variceal bleeding, hepatic encephalopathy, refractory ascites, spontaneous bacterial peritonitis, portal vein thrombosis, hepatorenal and hepatopulmonary syndromes and hepatocellular carcinoma. Chronic viral hepatitis, alcoholic and non-alcoholic steatohepatitis and haemochromatosis prove to be the leading causes of cirrhosis in developed countries.

Allocation policies for liver transplantation are important due to the global shortage of donor organs, particularly in areas where transplant facilities are limited, such as sub-Saharan Africa. LDLT has to some degree alleviated the limited availability of donor liver organs, a practice prominent in Asia. In 2002, the Organ Procurement Transplant Network in the United States of America implemented a liver allocation system which assists prioritization for liver transplantation. Acute liver failure and immediate post graft failure are prioritized indications of liver transplantation, whilst patients with chronic liver disease are listed and await transplantation according to the severity of their illness based on the Model for End-Stage Liver Disease (MELD) score. The MELD score is a reliable measure of mortality risk and disease severity employed in patients with ESLD for organ allocation. The adult liver transplant protocol used at WDGMC includes standardized pre-, intra-, and post-operative
measures, and immunosuppression protocols followed on recipients of DDLT. (Refer Appendix 1.1)

Numerous non-infectious and infectious complications occur post liver transplantation.\textsuperscript{1,4,13,15} Hepato-biliary complications include graft dysfunction, biliary leaks and strictures and recurrence of primary liver disease.\textsuperscript{5,13,15} The latter encompasses a spectrum of all causes of ESLD, malignancy and metabolic causes of liver disease.\textsuperscript{13,15}

Long term complications of immunosuppression can result in multi-system dysfunction, including endocrine involvement, renal disease, metabolic syndrome, accelerated atherosclerosis and metabolic bone disease.\textsuperscript{9,12,16} The incidence of metabolic syndrome post liver transplantation is twice as frequent when compared to the general population.\textsuperscript{9} Significant independent predictors of post transplantation metabolic syndrome described by Laish et al. include age, pre-transplant non alcoholic fatty liver disease, diabetes mellitus, body mass index and triglycerides.\textsuperscript{9} Hypertriglyceridemia is an early complication, occurring in the first month post transplantation, whereas hypercholesterolaemia occurs in the first 6 months.\textsuperscript{16} Myocardial infarction and cardiovascular death occurs more frequently in liver transplant recipients than age- and sex matched non-transplant individuals.\textsuperscript{12}

Hepatic and extrahepatic non-infectious complications in the early post-operative period following liver transplantation have been extensively published in international literature.\textsuperscript{9,12-16} Careful haemodynamic monitoring, fluid and electrolyte management and ventilatory support is crucial to minimize early post-operative complications.\textsuperscript{15} Failure of this can result in multi-organ complications.\textsuperscript{9,12,15,16} Inability to maintain metabolic homeostasis following liver transplant defines primary graft failure, a potentially fatal early complication.\textsuperscript{15} Both hypovolaemia and increased cardiac preload, often complicated by pulmonary oedema, can result in poor graft perfusion, an important risk factor for graft failure.\textsuperscript{15}

Acute cellular rejection (ACR) occurs most commonly within the first 2 weeks post liver transplantation, with a peak incidence at 7-10 days.\textsuperscript{33} The rare phenomenon of hyper acute rejection occurs within the first 48 hours due to preformed antibodies.\textsuperscript{15}
Biochemical findings (liver function tests) can be preserved in the face of ACR, a finding common to the early period. The globally accepted definition of ACR is histologically proven rejection 0-90 days following liver transplantation. Despite the discordant finding of normal biochemistry and histologically proven ACR, early protocol biopsies are no longer routinely advocated. Higher doses of immunosuppression therapy used to treat recurrent and chronic rejection is an important risk factor for the development of opportunistic infections.

Biliary leaks and obstruction are usually observed in the early post-operative period, whilst strictures are a later complication. Early biliary complications are classified as 0-4 weeks post transplantation, whereas late biliary complications occur thereafter, with both remaining a significant contributor of morbidity and mortality. Older donor age, increased cold and warm ischaemia time, surgical technical difficulties, presence of cytomegalovirus (CMV) infection pre-transplantation, ABO mismatch and donation after cardiac-related death are a few risk factors which predispose recipients to biliary complications post liver transplantation. Asymptomatic liver transplant recipients with elevated serum aminotransferase, bilirubin levels and ductal enzymes warrant further investigation to exclude biliary complications.

Saner et al. describes encephalopathy as the commonest neurological complication post liver transplant in the first month, followed by seizures. Neurological complications accounted for longer ICU stay compared to those with non-neurological complications. In this cohort, calcineurin inhibitor use did not significantly impact 30 day neurological outcomes.

Multifactorial aetiologies account for early renal complications, including hypovolaemia, sepsis, nephrotoxic drugs, underlying CKD, pre-existing hepato-renal syndrome and surgical complications. Acute kidney injury (AKI), a major cause of morbidity and mortality following liver transplantation, has a variable incidence of 5-94% following orthotopic liver transplantation (OLT), with approximately 8-17% requiring renal replacement therapy. The following independent risk factors for developing AKI post orthotopic liver transplantation are demonstrated by a Chinese study: blood loss, cold and warm ischaemia time, overexposure to calcineurin inhibitors (CNI) and combined immunosuppression
therapy (mycophenolate mofetil (MMF) and CNI use). The RIFLE or AKIN criteria were used to define AKI in this study, in accordance with the (Kidney Disease Improving Global Outcomes) KDIGO guidelines. This study did not demonstrate a significant relationship between MELD score, Child-Pugh score, pre-operative hypoalbuminaemia, cirrhosis, hepatic failure and duration of surgery and the development of AKI post transplantation. A 5 year retrospective study reveals an incidence of 52% of AKI within 72 hours post liver transplantation. Other reported risk factors for developing AKI 72 hours post transplantation include female gender, weight greater than 100kgs, high Child-Pugh score, presence of underlying diabetes mellitus and a greater number of units of blood transfusion or fresh frozen plasma.

Chronic kidney disease (CKD) is a well-documented complication following OLT and is associated with a higher mortality rate than liver transplant recipients without renal dysfunction. As liver transplant recipients’ survival increases, so does the incidence of renal dysfunction. Pre-transplantation serum creatinine level have been identified to predict post-OLT renal dysfunction and survival. A study in Pennsylvania suggests that the duration of renal dysfunction pre-OLT predicts recipients’ renal outcomes, which may help identify patients in need of combined liver kidney transplantation. The various causes of underlying CKD however did not prove significance. This study cohort’s spectrum of aetiology of underlying CKD included end stage hypertensive nephropathy, multifactorial glomerulonephritides, polycystic kidney disease, hepatorenal syndrome (HRS), lupus nephritis and drug induced nephropathy. A study in the USA documents the incidence of CKD in liver transplant recipients as 14% at 3 years and 18% at 5 years post transplantation. This study defined CKD as an estimated GFR <30 mL/min per 1.73 m². Risk factors for developing CKD in this cohort included CNI exposure, older age, female gender, post-operative acute renal failure, pre-existing hypertension, diabetes and hepatitis C infection. CNI exposure is a major risk factor for developing renal dysfunction post liver transplantation, while CNI dose reduction does not always improve renal function, but may delay progression of renal disease. A significant improvement in renal function can be seen if CNI therapy is substituted with MMF or sirolimus in individuals whom have not yet developed irreversible renal injury from CNI toxicity.
HRS, a serious complication of ESLD, requires prompt and aggressive medical treatment initiation, followed by liver transplantation. Comparable renal outcomes are seen in hepatorenal and non-hepatorenal individuals post liver transplantation. Mitzner et al suggests improvement in HRS type 1 with medical treatment using extracorporeal albumin dialysis with a molecular adsorbent recirculating system. HRS type 1 and a greater MELD score are usually associated with poorer outcomes, both entities being documented predictors of outcome. Combined liver-kidney transplantation for HRS remains controversial, a procedure generally performed on individuals with primary liver and kidney disease.

Of both infectious and non-infectious respiratory complications post liver transplantation, pleural effusions, atelectasis, pulmonary oedema and pneumonia are more commonly noted in the early post-operative period, contributing to morbidity and mortality. A multicenter prospective study however attributes only 2.4% of all mortalities to respiratory complications post liver transplantation. In this study, approximately 80% of all respiratory deaths are non-infectious related, while pneumonia is the leading infectious cause in this study. Acute respiratory distress syndrome (ARDS), an early complication, can be a manifestation of severe reperfusion syndrome, prolonged surgical time, significant blood loss and severe sepsis.

Infections following liver transplant have been widely published in both high and lower income countries. Post transplant infections contribute to significant morbidity and mortality, yet often remain preventable. Three periods following liver transplantation are associated with infections: within the first month, between 1 and 6 months and beyond 6 months.

Infection profiles in the first month following liver transplantation mimic those of an immune-competent host following surgery. In this time period bacterial infections are most prominent. Operative risks, extended hospitalization and donor transmitted diseases are amongst the common causes of infections. Roux-en-Y biliary anastomosis, prior multiple abdominal surgeries, the presence of post-operative CMV infection and graft dysfunction also confer an increased risk in developing bacterial infections post liver transplantation. Nosocomial sources of infection, donor-derived infections, diabetes mellitus, hypoalbuminaemia and cytomegalovirus (CMV)
seropositivity are risk factors for bacterial infections following liver transplant.\textsuperscript{1,5,11,15} Gram positive cocci and Enterobacteriaceae account for most bacterial pathogens,\textsuperscript{1} whilst the abdomen and lungs appear to be the predominant sites of infection.\textsuperscript{1,3,6}

Candida species, Clostridium difficile and herpes virus are frequently seen in the first month post liver transplantation.\textsuperscript{1,5} Globally, Candida species is the commonest cause of systemic fungal infections seen in liver transplant recipients.\textsuperscript{1,7} A review by Liu \textit{et al.} has proposed the following risk factors associated with systemic fungal infections in liver transplant recipients: acute renal failure requiring haemodialysis or haemofiltration, number of fresh frozen plasma units transfused, cytopaenias, CMV infection and prolonged surgery.\textsuperscript{7} Intensive immunosuppressive therapy remains the greatest predisposition to developing fungal infections\textsuperscript{1,7} and also commonly results in Clostridium difficile colitis.\textsuperscript{1,8} Importantly, higher doses of immunosuppression therapy used to treat recurrent and chronic rejection is an important risk factor for the development of these opportunistic infections.\textsuperscript{42} Immunosuppression related infections usually occur in the first 3 months post transplantation, the period of greatest immunosuppression.\textsuperscript{43,44} Antimicrobial use, frequent in the early post-operative period, is a risk factor for Clostridium difficile.\textsuperscript{8} Fungal infection post liver transplant is life threatening and can be challenging to diagnose antemortem.\textsuperscript{7}

Local data on liver transplantation and its early complications are scarce. A study from the liver transplant unit at GSH in Cape Town reviewed the first decade of liver transplants since its establishment in 1988.\textsuperscript{10} Eighty nine transplants were performed on eighty three individuals, with cirrhosis being the leading indication of transplant in the adult group.\textsuperscript{10} A favourable five-year survival rate of 64\% was reported, with a 72\% one-year graft survival rate.\textsuperscript{10} A pertinent infectious complication was de novo hepatitis B infection in recipients without evidence of hepatitis B infection prior to transplant.\textsuperscript{10} A significantly higher incidence of tuberculosis post transplantation was reported in this study, where tuberculosis is endemic, as compared to other studies worldwide.\textsuperscript{10} Rejection, bleeding and sepsis were the early complications causing immediate post-transplant mortality and accounted for 29\% of all deaths in this study.\textsuperscript{10}
A study at WDGMC currently in-press, reports 206 DDLT performed over the decade 2004-2013. This South African data demonstrates survival curves similar to those at international liver transplant centers where DDLT are performed. The predominant indication for liver transplantation in this series is primary sclerosing cholangitis. Biliary complications following DDLT appear most prominent in the study, followed by infectious complications. Early complications, defined as the first 100 days following surgery in this study, include graft rejection, infection and biliary leaks, the latter occurring most commonly immediately post-surgery. Hepatic artery thrombosis (HAT), predominantly occurring in the paediatric population, was noted as the most frequent vascular complication. Most cases of HAT were reported as early post-operative complications. The Donor Risk Index (DRI) was calculated in this study together with the MELD score, the former being more accurate in predicting poor survival following transplant. In this study, a prolonged theatre time, DRI of 1.8-2.0 and the presence of ascites at the time of transplant was associated with increased mortality in recipients.

There is limited literature on the outcomes of adult liver transplant programs in SA. Infections following liver transplantation remain an important cause of mortality in the early post transplantation period. Sepsis is defined and categorised by the CDC/NHSN guidelines. (Refer to Appendix 1.2) Emphasis on close surveillance for bacterial and fungal sepsis, early detection and adequate therapy remains pivotal in reducing mortality. It remains a clinical challenge to diagnose life-threatening infections in post-transplant recipients. Meticulous post-operative management with close haemodynamic, electrolyte and ventilatory monitoring is another area requiring awareness in order to improve morbidity and reduce mortality from non-infectious complications seen in the early post-operative period.

STUDY AIM and OBJECTIVES
The aim of this retrospective study is to describe all complications in adult DDLT recipients within the first month following liver transplantation performed at the WDGMC, for the two-year period 01 January 2015 – 31 December 2016. The objectives of this study are:
1) To identify and describe all complications in liver transplant recipients in the first month post transplantation.
2) To classify the complications as infectious or non-infectious causes within this time period.

3) To describe the microbiological profile of organisms causing infectious complications.

4) To describe and classify according to organ system all non-infectious complications.

5) To investigate the association between demographic data (age, gender), ascites and type 2 diabetes mellitus and the type of complication, for both infectious and non-infectious complications.

METHODS

This descriptive study will be conducted at Wits Donald Gordon Medical Centre (WDGMC). A retrospective database, clinical record and ICU chart review of all adult liver transplants during the period 2015-2016 will be conducted.

The following variables will be collected from the records:
Demographic: age, gender
Medical information: indication for liver transplant, MELD score, presence of diabetes, ascites and CMV status.
Transplant: date of transplant
Mortality: mortality in the first month post-transplant, date of death, cause of death
Duration of ICU stay
For infectious complications post-transplant in the first 30 days:
  Presence of infection\(^{52}\) (defined as per appendix 1.2)
  Antibiotic administration (empiric\(^{51}\) and culture directed antibiotic use)
  Microbiological profile of infection
  Source of sepsis\(^{52}\) to be documented
  Microbiological reports and serological markers of infection will be retrieved from the 4 laboratories involved in processing microbiologic specimens (Ampath Pathologists, Vermaak and Partners Pathologists, NHLS and Lancet Laboratories). Results tabulated as per Appendix 1.3.

Non-infectious complications within the first 30 days will be tabulated as per appendix 1.3. For all deaths within the first 30 days following liver transplantation the cause of
death will be documented, either from the available post mortem reports or from clinical records.

DATA ANALYSIS
Objectives 1) and 4): For the categorical variables, the frequency and percentages will be computed.
Objective 2): To compare the proportions of infectious and non-infectious complications, a chi-squared test of comparison will be used.
Objective 3): For continuous variables such as age, the Shapiro Wilk test of normality will be used to assess the distribution of data and where appropriate, the mean/standard deviation, median/interquartile range will be computed.
Objective 5): to fulfill this objective, univariate and/or multivariate logistic regression models will be fitted.

ETHICS
Ethical clearance will be applied for to the Human Ethics Research Committee of The University of the Witwatersrand.

TIMING
The start of the project will be determined by approval from the HERC and the Faculty’s Research Committee.
FUNDING
This retrospective study does not require added funding. No new intervention or added testing is required. Any incidental costs such as travel and photocopying will be borne by the researcher.

ANTICIPATED CHALLENGES
Record review relies on information available on the current WDGMG liver transplant database. Information not available from this database limits accuracy of this study.

Background
Deceased donor liver transplants (DDLT) are the only type of liver transplants performed in adults at WDGMC. Infections, graft dysfunction, biliary, gastro-intestinal tract (GIT), vascular, renal, respiratory and neurological complications are the most common complications in the early post-transplant period and account for most of the early morbidity and mortality.

Objectives
Firstly, to provide a descriptive analysis of all complications occurring in the first thirty days post operatively in adult liver transplant recipients. Secondly, to investigate any association between recipient demographic data (age and gender), ascites, diabetes and MELD score and subsequent complications.

Methods
A retrospective chart review of all adult DDLT recipients for the first thirty days post-transplant was performed at WDGMC for the period January 2015 to December 2016. Complications were classified as infectious or non-infectious. Categorical and continuous variables were analyzed. Fischer's exact test was used to assess the relationship between demographic data and the presence or absence of infectious complications, while independent sample t-test was used for non-infectious complications.

Results
78 DDLT were performed, with 6 mortalities (8%) in the first 30 days post transplantation. The median length of ICU stay was 6 days (range 2-30 days). The median age of transplant recipients was 54 years, with 54% males. In total 24 patients (31%) had infectious complications in the first 30 days. 16 patients (67% of the infectious cohort) had intra-abdominal sepsis. 6 patients (25%) had lower respiratory tract infections, 6 (25%) had skin and soft tissue infections and 3 (13%) had urinary tract infections. Of all infectious complications, 7 patients (29% of the infectious cohort) developed bacteraemia. In total 55 patients (71%) had non-infectious complications. The most common was renal complications which occurred in 37 patients (67%). 33 patients (60%) had GIT (hepatic, biliary and intestinal), 24 patients (44%) had respiratory, 13 (24%) had neurological, 10 patients
(18%) had vascular, 11 patients (20%) had haematological, and 6 patients (11%) had cardiac complications respectively. 13 patients (24%) developed tacrolimus toxicity and 2 patients (4%) had other drug reactions. Acute rejection was suspected in 3 patients (5%). There was no significant association between any of the demographic variables (age, gender), ascites, diabetes mellitus, MELD score and the presence or absence of any complications (infectious and/or non-infectious).

**Conclusion**

This comprehensive report from South Africa documents complications that occurred within 30 days post liver transplantation in adult recipients. Non-infectious complications occurred more commonly than infectious complications (71% vs. 31%). The most common infectious complication was intra-abdominal sepsis, and the most common non-infectious complication was renal dysfunction. There was no significant association between any of the demographic variables (age, gender), ascites, diabetes mellitus and MELD score and the presence or absence of any complications.
Introduction

1963 marks the first human liver transplant. In adults, deceased donor liver transplants (DDLT) are the only type of transplant performed in sub-Saharan Africa, whilst living donor liver transplants (LDLT) are routinely performed worldwide. LDLT has alleviated the limited availability of donor liver organs, a practice prominent in Asia.

There are only two adult liver transplant centers in sub-Saharan Africa, Groote Schuur Hospital in the Western Cape and Wits Donald Gordon Medical Centre (WDGMC), both in South Africa. The adult liver transplant protocol used at WDGMC includes standardized operating procedures and immunosuppressive therapy for recipients of DDLT in the pre-, intra, and post-operative periods. (Refer to appendix 1.1)

Numerous non-infectious and infectious complications occur post liver transplantation. Careful haemodynamic monitoring, fluid and electrolyte management and ventilatory support is crucial to minimize early post-operative complications. Failure of this can result in multi-organ complications. Inability to maintain metabolic homeostasis following liver transplant defines primary graft failure, a potentially fatal early complication. Biliary leaks, biliary obstruction and hepatic artery thrombosis, are some of the most common hepato-biliary complications in the early post-operative period following liver transplantation.

Complications of immunosuppression can result in sepsis, multi-organ dysfunction and graft failure. Post transplant infections are a significant contributor of morbidity and mortality, yet remain potentially preventable. Three periods following liver transplantation are associated with different infection profiles: within the first month, between 1 and 6 months and beyond 6 months. Infections in the first month following liver transplantation mimic those of an immune-competent host, following surgery. In this time period bacterial infections are most prominent. Operative risks, extended hospitalization and donor transmitted diseases are amongst the common risk factors for development of infections. Hospital acquired pathogens, donor-derived infections, diabetes mellitus, hypoalbuminaemia and cytomegalovirus (CMV) seropositivity are risk factors for bacterial infections following liver transplant.
Preliminary data from a study in press at WDGC, indicates that fungal infections are implicated in infection related mortalities, especially within the early post-operative period. Globally, *Candida* species, is the commonest cause of systemic fungal infections seen in liver transplant recipients. Following bacterial infections, *Clostridium difficile* and herpes virus are seen in the first month post-transplant.

There is very little literature on the outcomes of adult liver transplant programs in SA. Emphasis on anticipation of sepsis, particularly bacterial and fungal, early detection and adequate therapy remains pivotal in prevention of mortality. Meticulous post-operative management with close haemodynamic, electrolyte and ventilatory monitoring is another area requiring awareness in order to improve morbidity and reduce mortality from non-infectious complications seen in the early post-operative period.

**Aim**

To provide a descriptive analysis of all complications occurring in the first thirty days post operatively in adult liver transplant recipients at Wits Donald Gordon Medical Centre (WDGMC).

**Materials and Methods**

1. **Study population**

A retrospective chart review was conducted on all adult DDLT recipients for the first thirty days post-transplant. This was performed at WDGC for the period January 2015 to December 2016. Permission to conduct the review was granted by the University of Witwatersrand Human Research Ethics Committee (Medical), approval certificate M170265 as included in appendix 1.4.

2. **Data collection**

The following information from all adult DDLT recipients was documented: age, gender, indication for transplant, presence of ascites, diabetes mellitus (DM) (types 1-3), hepatitis status (including A-C) and CMV status. CMV status from donors was obtained. Length of ICU stay was documented, up to the period of thirty days. Following liver transplantation, hospital charts and laboratory results were reviewed for the first 30 days, reporting all complications that occurred. This included death within the first 30 days. Non-infectious complications were reported by organ
involvement, as per the attached data collection sheet. (Refer Appendix 1.3) Due to the variety of complications noted, each organ system contained a category entitled “other”, as only the most frequent complications were categorized solely. Infectious complications were identified upon chart review and correlated with serological/microbiology findings. Diagnoses and antibiotic use found on chart reviews were documented. Infectious pathogens, susceptibility to antimicrobial agents and site of infection were identified from the available microbiology reports, hospital charts, clinical information and serology reports. Site of infection was categorized according to the CDC/NHSN guidelines.\textsuperscript{31} (Refer to Appendix 1.2) Empiric\textsuperscript{30} and/or directed anti-microbial therapy was documented. Patients with positive blood cultures were also recorded. Post mortem reports for the causes of death were requested from the forensic pathology department.

3. Assays
Analyses of blood serum samples and microbiology reports were performed by the following accredited laboratories according to good laboratory practice: South African National Health Laboratory Services (NHLS), Ampath Laboratories, Lancet Laboratories and Vermaak and Partners Pathologists. Where applicable, adult reference ranges were applied for the various blood tests.

4. Definitions
Adult cases referred to individuals 18 years and older.
The CMV status of donors was considered positive if the screening pre-donation serum CMV IgG serology was positive.
Hepatitis A status was considered positive if the hepatitis A Antibody serology was positive.
Chronic Hepatitis B status was considered positive if the hepatitis B surface antigen serology was positive and the hepatitis core IgM serology was negative.
Hepatitis C status was considered positive if the individual had a positive hepatitis C antibody serology and a positive hepatitis C viral load PCR.
Infection and infectious complications were classified according to the CDC/NHSN definition of sepsis and criteria for sepsis as attached in Appendix 1.2.\textsuperscript{31}
As this project reviewed patients for the duration of only 30 days post transplantation, the length of ICU stay was truncated to 30 days, despite the possibility of exceeding this duration.

Length of ICU stay incorporated both ICU and High Care stay.

Directed antimicrobial therapy was defined as culture directed therapy, with confirmed susceptibility to the diagnosed pathogen.

Empiric antimicrobial therapy was defined as therapy based on clinical suspicion, in the absence of an identified pathogen and antimicrobial susceptibility.30

5. Statistical analysis

Data was analysed using SAS version 9.4 for windows. Categorical and continuous variables were used for this descriptive analysis. The former was represented by frequency and percentage tabulation and demonstrated on bar charts. Mean, standard deviation, median and interquartile range (IQR) represent continuous variables. Histograms were used to illustrate their distribution. The relationship between the presence/absence of infectious/non-infectious complications and age, DM in a recipient, ascites, and hepatitis status of both donor and recipients was depicted using Fischer’s exact test. For the above, the phi coefficient measures the strength of association. Independent samples T test was used to assess the relationship between the presence/absence of infectious/non-infectious complications with age and MELD score. Cohen’s d was used to measure the strength of association. Results were taken as statistically significant for p-values of less than 0.05.

Results

In the current study, in which 78 adult liver transplant recipients were retrospectively identified and reviewed over a two-year period, 63 recipients (81%) developed complications within the first month post orthotopic liver transplantation (OLT). Sixteen recipients of the 63 (25%) had 1 complication only, whilst the remainder experienced multiple complications. Twenty-four patients (31%) developed infectious complications and 55 patients (71%) developed non-infectious complications, respectively. Chronic liver cirrhosis with ESLD, diagnosed in 70 recipients (89%), was the most common indication for liver transplants in this cohort, with some individuals
having more than 1 underlying indication, as seen in figure 1. In this cohort, the 3 commonest causes of cirrhosis included: non-alcoholic fatty liver disease (NAFLD) (n=20, 29%), chronic viral hepatitis (n=19, 16%) and biliary pathology (n=14, 20%). Only 4 individuals (5%) required emergency liver transplantation due to acute fulminant liver failure.

**Demographics, comorbidities and complications post transplantation**

The median age of the 78 adult liver transplant recipients was 54 years (IQR 39-60). Fifty transplants (64%) were performed on male patients. The presence of ascites and DM pre-transplantation occurred in 36 recipients (46%) and 19 recipients (24%), respectively. Fifty-seven donors (73%) had a positive CMV serology status. The presence of diabetes mellitus, in 4 individuals (17%) of the infectious cohort and 15 (24%) of the non-infectious cohort, did not prove to be statistically associated with complications, as represented in figures 10,12. The median MELD score of recipients pre-transplant was 20 (IQR 15-24). Of all 78 liver transplants performed, 6 (8%) resulted in mortality in the first thirty days post transplantation. The median length of ICU stay post transplantation was 6 days for the entire cohort. The median length of ICU stay for those who died within the first 30 days was 13 days (Range 7-30d). No association was found between continuous variables (age, pre-transplant MELD score) and infectious complications, as demonstrated by high p-values in figure 11. Likewise, no statistically significant association was evident when comparing these variables with non-infectious complications, also depicted in figure 11. Categorical variables (gender, diabetes mellitus, ascites, hepatitis) compared to the presence/absence of infectious and non-infectious complications also proved to be statistically insignificant as evident by high p-values in figure 12.

**Patients with infectious complications (n=24)**

In the first 30 days following liver transplantation, infectious complications (n=24, 31%) were less frequently seen than non-infectious complications (n=55, 71%), as represented in figure 2. As noted in figure 3, the majority of patients who developed infectious complications (n=16) developed intra-abdominal sepsis, accounting for 67% of the infectious complication cohort. Six (25%) of the transplant recipients who developed infectious complications were found to have lower respiratory tract infections. The same number of recipients also developed skin and soft tissue
infections (25%). Three recipients (13%) developed urinary tract infections. Seven patients of the infectious complication cohort (29%) developed a bacteraeemia. In 10 recipients of the infectious complication cohort (42%), sepsis was clinically suspected but no specific pathogen was identified. Of the 14 recipients (58%) with pathogen proven infection, 100% were bacterial. In the 24 recipients with infectious complications, the most common antimicrobial therapies used were meropenem (n=15) and tigecycline (n=13). Fifteen recipients (63%) received directed antimicrobial therapy, 6 (25%) received empiric therapy, and 5 (21%) received both empiric and directed antimicrobial therapy as empiric therapy was considered appropriate and continued following available microbiology reports. *Klebsiella pneumoniae* was the commonest organism, isolated in 11 patients (46% of the infectious cohort). Ninety percent of infections due to *Klebsiella pneumoniae* had an intra-abdominal source, as reflected in figure 4. Access to post-mortem reports was not available and all cases of infectious complications (n=24) were diagnosed ante mortem.

**Patients with non-infectious complications (n=55)**

As demonstrated in figure 5, renal complications were the most frequently encountered non-infectious complication (n=37, 67% of the non-infectious cohort). This was followed by 33 recipients in whom GIT complications developed, which accounted for 60% of the non-infectious cohort. Thereafter, in descending frequency with percentages of the non-infectious complication cohort: respiratory complications (n=24, 44%), neurological complications and tacrolimus toxicity, both occurred in 13 patients each (24%), haematological (n=11, 20%), vascular (n=10, 18%), cardiac and graft failure both occurred in 6 recipients (11%), suspected acute rejection (n=3, 5%), and other drug reactions (n=2, 4%).

Of the renal non-infectious complications, as seen in figure 6, acute kidney injury (AKI) proved the most common finding (n=39, 71%). Sixteen recipients (42%) in the non-infectious cohort with renal complications experienced an infectious complication too. In 8 recipients (22%) the renal complications were considered to be directly due to sepsis. AKI not requiring dialysis appeared more prevalent than AKI requiring acute dialysis, (n=21, 38% and n=18, 33% respectively). Of all non-infectious GIT complications, hepatic complications developed most commonly (n=12, 22%),
followed by GIT bleed (n=10, 18%), biliary (n=8, 15%) and intestinal complications (n=7, 13%), as per figure 7. Of all the non-infectious respiratory complications (n=29), pleural effusions occurred most frequently (n=22), of which 64% were drained, as reflected in figure 8. Delirium was the most common neurological complication (n=11, 85% of all neurological complications). Of all vascular complications, illustrated in figure 9, hepatic artery thrombosis (n=6) was most prevalent, followed by portal vein complications (n=2), IVC complications (n=2) and other (n=1). Eleven patients (20% of the cohort with non-infectious complications) developed haematological complications, of which pancytopenia (n=6, 55%) was the most frequent finding. Cardiac complications occurred in 6 recipients (11%), with cardiac failure being the most common finding (n=5, 83%). Graft failure (n=6) occurred in 11% of the non-infectious complication cohort. Drug reactions (n=2, 4%) occurred least commonly in this study. Acute rejection was clinically suspected in 3 patients (5%), but not biopsy proven within the 30day period of review.

Discussion
Local data on liver transplantation and its early complications remains scarce.4,10 To date, there are very few local epidemiological studies assessing the outcomes post liver transplantation.4,10 This is the first comprehensive 30 day report from Africa of all complications occurring in DDLT recipients following transplantation. The time period of 30 days post transplantation focuses on complications seen predominantly within the ICU/High Care setting. In our cohort of 78 adult recipients, it is unsurprising that the major indication for liver transplantation is ESLD and cirrhosis. Cirrhosis, the result of numerous causes of ESLD, accounts for approximately 80% of all indications for liver transplantation throughout the USA,17 consistent with this study. The increasing prevalence of obesity, diabetes and hyperlipidaemia in western countries contributes to the greater prevalence of NAFLD.32 NAFLD is therefore estimated to occur 20-30% more frequently in western countries.32

In this cohort, non-alcoholic fatty liver disease (NAFLD) is the leading cause of cirrhosis (n=20, 29%), followed by chronic viral hepatitis (n=19, 16%) and biliary cirrhosis (n=14, 20%). This differs slightly from data published in both developing and developed countries, which indicate that hepatitis B and C, alcoholic steatohepatitis and hepatocellular carcinoma are the most common indications for liver
transplantation, in descending frequency.\textsuperscript{4} Findings from local data at WDGMC and that published from Cape Town also differ, with primary sclerosing cholangitis and alcoholic steatohepatitis accounting for the most common causes of end stage cirrhosis requiring liver transplantation.\textsuperscript{4,10} These studies include both adult and paediatric populations,\textsuperscript{10} a possible reason for higher incidences of biliary disease, which is common to the paediatric population.\textsuperscript{10} Possible contributors to the higher proportion of NAFLD in this study are the exclusive adult population and presence of type 2 DM (24\%). Importantly, obesity is prevalent amongst South African adults, particularly females,\textsuperscript{33} another possible reason of NAFLD, despite the male predominance in this cohort (64\%). Unfortunately body mass index was not reliably documented at the time of transplantation in this cohort, but is frequently in range of 28-35 in the pre-transplant work up stage (personal communication Dr GK Schleicher).

This study reveals non-infectious complications (71\%) to occur more commonly than infectious complications (31\%) within the first 30 days post transplantation, differing from findings of the ten year retrospective review from WDGMC, currently in press.\textsuperscript{4} The significantly shorter time frame (30d) of this study influences this finding, a period in which patients are susceptible to both acute infectious and non-infectious complications. Complications such as biliary strictures, CKD, CNI toxicity and opportunistic infections are a few anticipated complications expected over a longer time period of review, as per the WDGMC decade study.\textsuperscript{4,10,15,24-26} Non-infectious biliary complications (20.9\%) followed by infectious complications (19.9\%) and vascular complications (17.5\%) proved the most common outcomes from the decade review,\textsuperscript{4} while renal (47\%), GIT (42\%), respiratory and infectious complications (31\% each) are the most frequent findings of this study, as expressed as percentages of the total cohort (n=78). Vascular complications are expected to occur less frequently in this study, due to the short review period of this study.\textsuperscript{4,27}

Importantly, biliary complications are reported as a component of GIT complications in this study. Biliary complications are approximately 50\% lower in this study (10\%) than the WDGMC decade-review.\textsuperscript{4} Biliary leaks and obstruction are observed as early as 1 month post transplantation, while strictures tend to occur later, one of the likely reasons for this discordant finding.\textsuperscript{15,26} These findings are however still consistent with
the reported incidence of 10-25% of biliary complications following liver transplantation in developed countries.\textsuperscript{19-25}

Hepatic artery thrombosis (HAT), the most frequent vascular complication (8%), parallels findings from the decade retrospective review performed at WDGMC.\textsuperscript{4} The decade review reports an incidence of 5.3% of early HAT, which accounts for majority of vascular complications (17.5%).\textsuperscript{4} Early HAT is defined as 0-100 days post-transplant in this decade-review.\textsuperscript{4} A systematic review of 77 studies from developed and developing countries reports a lower incidence (2.9%) of early HAT (defined as the first 60 days) in adult liver transplant recipients.\textsuperscript{27} The age references for paediatric and adult populations are not clearly defined in the systematic review.\textsuperscript{27} This systematic review acknowledges a higher incidence of early HAT to occur in DDLT vs. LDLT, the latter being the major representation of trials reviewed.\textsuperscript{27} The decade review performed in Cape Town, which includes both adult and paediatric groups, also revealed a low incidence of HAT (3.4%).\textsuperscript{10} Despite DDLT being the only type of transplant performed in this study, the low incidence of early HAT is attributed to microsurgical techniques, routine post-transplant thrombo-embolism prophylaxis and the administration of aspirin in the paediatric population.\textsuperscript{10}

This study reveals a 51% incidence of AKI post transplantation, consistent with studies from the USA, which report an incidence of 5-50%.\textsuperscript{7,28} The incidence of renal complications was much lower (3.54%) in the retrospective decade-review at WDGMC, accounting for recipients with AKI requiring haemodialysis only,\textsuperscript{4} considerably lower than this study’s incidence of recipients requiring haemodialysis due to AKI (23%). Twenty two percent of recipients developed renal complications (AKI) secondary to sepsis. Bacterial infections are highly anticipated in the first month following liver transplantation, a time frame consistent to this study.\textsuperscript{4,10} Sepsis leading to haemodynamic instability, hypoperfusion and acute tubular necrosis remain important contributors of renal complications,\textsuperscript{3,7,12,14-16} highlighted in this study. Complications other than AKI requiring dialysis, aetiology of renal dysfunction and CNI toxicity requiring change in immunosuppressive therapy remain unreported by the decade review.\textsuperscript{4} Twenty five percent of recipients with renal complications had underlying DM, an association that did not prove statistically significant to this study.
The small sample size appears to be one of the greatest limitations in proving statistical significance between the presence of DM and renal dysfunction.

Findings of respiratory complications are inconsistent between this study and the decade-review done at WDGMC.\textsuperscript{4} This study's higher incidence of respiratory complications (37\%) is predominantly attributed to pleural effusions, whilst the 6.8\% incidence of respiratory complications noted in the WDGMC decade-review are a result of thromboembolism, as well as unspecified aetiologies requiring ventilation.\textsuperscript{4} The lack of extensive categorical data in other studies limits data comparison to this comprehensive descriptive study.

Larger cohort studies demonstrate an incidence of 10-70\% of acute rejection,\textsuperscript{2} findings much higher than this study (4\%) and the WDGMC decade review (11.7\%).\textsuperscript{4} Liver biopsies were not routinely performed during this study's period of review, with the presumptive diagnosis of acute rejection based on clinical and biochemical findings (liver function tests and international normalized ratio). Importantly, this study's limitations include its duration of review, recipients who have normal biochemistry despite possible underlying ACR and the time frame (0-90d) of the globally accepted definition of ACR.\textsuperscript{4,8}

Bacterial infections as the predominant cause of infection in this study, within the first month post transplantation, concurs with literature worldwide.\textsuperscript{1,4,5} Ten recipients (42\%) of the infectious complication cohort had no specific identifiable pathogen, yet were clinically suspected to have infections. Sepsis with multi-organ failure was present in all cases of death in this cohort (8\%). Fungal sepsis was considered to play a role in these patients with early mortality, based on positive beta-d-glucan serology and the poor response to broad spectrum antibiotics. However, this was not confirmed microbiologically and post mortem reports are unavailable to confirm the authors' suspicion of systemic fungal sepsis. The clinical limitation to accurately diagnose and microbiologically confirm life-threatening infections in recipients post solid organ transplantation remains an ongoing challenge.

Both South African studies reviewing outcomes over a 10-year period reveal a predominance of bacterial infections over viral and fungal infections.\textsuperscript{4,10} This differs
with the well documented emergence of viral and fungal infections seen more commonly following 1 month after transplantation.\textsuperscript{1,5} The findings of this study concur with international studies, reporting the commonest sites of infection as abdominal and lung in the first month post transplantation.\textsuperscript{3,6} The frequent complication of bacteraemia following infection in these particular sites is also comparable to this cohort.\textsuperscript{3,6} In this study, 67% of all infections are intra-abdominal, 25% skin and soft tissue and 25% lower respiratory tract infections. Interestingly, 83% of all skin and soft tissue infections were reported to originate from the surgical abdominal wound, consistent with international reports.\textsuperscript{3,6} Furthermore, in keeping with international data,\textsuperscript{3,6} 60% of all cases of bacteraemia have an intra-abdominal source of infection, whilst 20% have a lower respiratory source and the remaining 20% due to urinary tract infections.

Despite extensive documentation of the direct association between bacterial infections in the first month post transplantation and DM, hypoalbuminaemia, CMV seropositivity and donor derived infections,\textsuperscript{1,5,11,15} this study could not confirm this association. However, ascites appears to negatively predict recipient and graft survival (P value 0.011 and hazard ratio 3.06) in the retrospective decade review done at WDGMC.\textsuperscript{4} It is the author’s assertion that the small sample size is a probable limitation of this retrospective review.

This cohort revealed a mortality of 8\% of all recipients at 30 days post-transplant, unfortunately without access to post mortem reports. The trend toward improving survival, with decreasing death as time progresses is comparable to both local and international data.\textsuperscript{4} The 30 day period of review provides limitation for comparisons of recipient survival to other studies.

**Conclusion**

This comprehensive report from Africa documents all complications occurring within 30 days post liver transplantation in adult recipients. Non-infectious complications occurred more commonly than infectious complications in the first 30 days post DDLT. There was no significant association between any demographic variables (age, gender), underlying ascites, diabetes mellitus and CMV status and complications.
Way forward
Despite the limitations of this study, these findings add valuable epidemiological information to the paucity of data that exists on complications in adult liver transplant recipients in sub-Saharan South Africa, particularly in the intensive care unit. Future plans include a larger prospective review over a longer time frame, with attention to causes of mortality, with the aim of deriving morbidity and/or mortality indices/scores to provide better outcomes for DDLT recipients.

CHAPTER 3 APPENDICES

1.1 Liver Transplant Protocol

Appendix A

Adult Liver Transplant Protocol

Pre-op:
- No patient to be accepted without prior discussion with ICU consultant and nursing shift leader (to ensure bed availability and intensivist cover)
- Inform Blood bank (5666) of transplant and of patient’s Blood Group (find out from transplant co-ordinator)
- Admission bloods: FBC, U&E, CMP, random Glucose, LFT, PI/PTT, CRP, PCT, Fibrinogen, Compat
- Order 10 units Packed cells (leukodepleted), 10 units FFP, and 3 Mega-units Platelets as Red Label Blood stat (Trenstar 5999)
- CXR, ECG
- NPO
- Consent
- Get patients’ Transplant File from transplant co-ordinator

Intra-op:
- Induction of immunosuppression with Zenepax 75mg IV STAT + Solumedrol 1g IV STAT on induction

Post-op:
- Often ventilated due to acidosis and high lactates. Start with BILEVEL ventilation (PEEP=10, TV=6-8ml/kg). Change to Spontaneous Assisted Breathing as soon as patient is awake and responsive. Extubate when metabolically and haemodynamically stable.
- Run 1L 5% D/W with 150ml 8.5% Sodabic (if acidotic), or Balsol (if not acidotic and normal potassium) at 100ml/hr
- Stress Ulcer prophylaxis with Nexiam 40 mg IV BD
- Morphine titration for pain (NO Perfalgan or NSAIDS)
- Dipeptivan 100mg IV BD over 4 hrs each
- Albosol 20% IV @ 10-20 ml/hr
- Fluid bolus (use Voluven) and/or Dobs if MAP <70 mmHg
- Hourly HGT and insulin infusion
- 4 hourly ABG
- Start maintenance immunosuppression:
  - Solu-Medrol 40mg IV QID – wean steroids over 5-6 days down to Prednisone/Methylprednisolone 40mg daily
- Prograf 1mg NGT/PO BD - Adjust Prograf dose daily to achieve Tacrolimus trough levels of 6-8.
  - Cellcept 1g IV BD – change to oral Cellecept 1g PO BD
  - Repeat Zenepax 75mg IV on D5

- Prophylaxis:
  - Valcyte 450mg PO BD (not NGT)
  - Bactrim 1 tab PO dly
  - Fluconazole 200mg IV/PO dly
1.2 CDC/NHSN DEFINITION AND CRITERIA FOR SEPSIS

CDC/NHSN surveillance definition of health care–associated infection and criteria for specific types of infections in the acute care setting

Teresa C. Horan, MPH, Mary Andrus, RN, BA, CIC, and Margaret A. Dudeck, MPH

Atlanta, Georgia

CDC/NHSN SURVEILLANCE DEFINITION OF HEALTH CARE–ASSOCIATED INFECTION

For the purposes of NHSN surveillance in the acute care setting, the CDC defines an HAI as a localized or systemic condition resulting from an adverse reaction to the presence of an infectious agent(s) or its toxin(s). There must be no evidence that the infection was pre-sent or incubating at the time of admission to the acute care setting.

HAIs may be caused by infectious agents from endogenous or exogenous sources.

d Endogenous sources are body sites, such as the skin, nose, mouth, gastrointestinal (GI) tract, or vagina that are normally inhabited by microorganisms.

d Exogenous sources are those external to the patient, such as patient care personnel, visitors, patient care equipment, medical devices, or the health care environment.

Other important considerations include the following:

d Clinical evidence may be derived from direct observation of the infection site (eg, a wound) or review of information in the patient chart or other clinical records. For certain types of infection, a physician or surgeon diagnosis of infection derived from direct observation during a surgical operation, endoscopic examination, or other diagnostic studies or from clinical judgment is an acceptable criterion for an HAI, unless there is compelling evidence to the contrary. For example, one of the criteria for SSI is “surgeon or attending physician diagnosis.” Unless stated explicitly, physician diagnosis alone is not an acceptable criterion for any specific type of HAI.

d The following infections are not considered health care associated:

s Infections associated with complications or extensions of infections already present on admission, unless a change in pathogen or symptoms strongly suggests the acquisition of a new infection;

d The following conditions are not infections: Colonization, which means the presence of microorganisms on skin, on mucous membranes, in open wounds, or in excretions or secretions but are not causing adverse clinical signs or symptoms; and inflammation that results from tissue response to injury or stimulation by noninfectious agents, such as chemicals.
Table 1. CDC/NHSN major and specific types of health care-associated infections

**UTI Urinary tract infection**
SUTI Symptomatic urinary tract infection
ASB Asymptomatic bacteriuria

Criteria for specific types of infection

Once an infection is deemed to be health care associated according to the definition shown above, the specific type of infection should be determined based on the criteria
detailed below. These have been grouped into 13 major type categories to facilitate data analysis. For example, there are 3 specific types of urinary tract infections (symptomatic urinary tract infection, asymptomatic bacteriuria, and other infections of the urinary tract) that are grouped under the major type of Urinary Tract Infection. The specific and major types of infection used in NHSN and their abbreviated codes are listed in Table 1, and the criteria for each of the specific types of infection follow it.

**UTI-URINARY TRACT INFECTION SUTI-Symptomatic urinary tract infection**

A symptomatic urinary tract infection must meet at least 1 of the following criteria:

1. Patient has at least 1 of the following signs or symptoms with no other recognized cause: fever (.388C), urgency, frequency, dysuria, or suprapubic tenderness and patient has a positive urine culture, that is, $10^5$ microorganisms per cc of urine with no more than 2 species of microorganisms.

2. Patient has at least 2 of the following signs or symptoms with no other recognized cause: fever (388C), urgency, frequency, dysuria, or suprapubic tenderness

and $\geq 10^5$ at least 1 of the following

1 positive dipstick for leukocyte esterase and/ or nitrate $\geq 10^5$

2 pyuria (urine specimen with $\geq 10$ white blood cell [WBC]/mm$^3$ or $\geq 3$ WBC/high-power field of unspun urine) $\geq 10^5$

3 organisms seen on Gram’s stain of unspun urine $\geq 10^5$

4 at least 2 urine cultures with repeated isolation of the same uropathogen (gram-negative bacteria or Staphylococcus saprophyticus) with $10^2$ colonies/mL in non-voided specimens $\geq 10^5$

5 $\geq 10^5$ colonies/mL of a single uropathogen (gram-negative bacteria or S saprophyticus) in a patient being treated with an effective antimicrobial agent for a urinary tract infection $\geq 10^5$

f. physician diagnosis of a urinary tract infection

g. physician institutes appropriate therapy for a urinary tract infection.

**BSI-BLOODSTREAM INFECTION**

LCBI-Laboratory-confirmed bloodstream infection

LCBI criteria 1 and 2 may be used for patients of any age, including patients #1 year of age.

LCBI must meet at least 1 of the following criteria:

1. Patient has a recognized pathogen cultured from 1 or more blood
cultural organism cultured from blood is not related to an infection at another site. (See Notes 1 and 2.)

2. Patient has at least 1 of the following signs or symptoms: fever (38.8°C), chills, or hypotension and 1 sign and symptoms and positive laboratory results are not related to an infection at another site and a common skin contaminant (i.e., diphtheroids [Corynebacterium spp], Bacillus [not B anthracis] spp, Propionibacterium spp, coagulase-negative staphylococci [including S epidermidis], viridans group streptococci, Aerococcus spp, Micrococcus spp) is cultured from 2 or more blood cultures drawn on separate occasions. If common skin contaminant organisms from the cultures are speciated but no anti-biograms are done or they are done for only 1 of the isolates, it is assumed that the organisms are the same. If the common skin contaminants from the cultures have anti-biograms that are different for 2 or more antimicrobial agents, it is assumed that the organisms are not the same. For the purpose of NHSN anti-biogram reporting, the category interpretation of intermediate (I) should not be used to distinguish whether 2 organisms are the same.

CSEP-CLINICAL SEPSIS

CSEP may be used only to report primary BSI in neonates and infants. It is not used to report BSI in adults and children.

PNEU-PNEUMONIA

There are 3 specific types of pneumonia: clinically defined pneumonia (PNU1), pneumonia with specific laboratory findings (PNU2), and pneumonia in immunocompromised patients (PNU3). Listed below are general comments applicable to all specific types of pneumonia, along with abbreviations used in the algorithms and reporting instructions. Table 8 shows threshold values for cultured specimens used in the surveillance diagnosis of pneumonia.

BJ-BONE AND JOINT INFECTION BONE-Osteomyelitis

Osteomyelitis must meet at least 1 of the following criteria:

1. Patient has organisms cultured from bone.

2. Patient has evidence of osteomyelitis on direct examination of the bone during a surgical operation or histopathologic examination.

3. Patient has at least 2 of the following signs or symptoms with no other recognized cause: fever (38.8°C), localized swelling, tenderness, heat, or drainage at suspected site of bone infection; and at least 1 of the following: a. organisms cultured from blood; b. positive blood antigen test (e.g., H influenzae, S pneumoniae)

JNT-Joint or bursa

Joint or bursa infections must meet at least 1 of the following criteria:
1. Patient has organisms cultured from joint fluid or synovial biopsy.

2. Patient has evidence of joint or bursa infection seen during a surgical operation or histopathologic examination.

3. Patient has at least 2 of the following signs or symptoms with no other recognized cause: joint pain, swelling, tenderness, heat, evidence of effusion or limitation of motion and at least 1 of the following:
   a. organisms and white blood cells seen on Gram's stain of joint fluid
   b. positive antigen test on blood, urine, or joint fluid
   c. cellular profile and chemistries of joint fluid compatible with infection and not explained by an underlying rheumatologic disorder
   d. radiographic evidence of infection (eg, abnormal findings on x-ray, CT scan, MRI, radionuclear scan [gallium, technetium, etc]).

DISC-Disc space infection

Vertebral disc space infection must meet at least 1 of the following criteria:

1. Patient has organisms cultured from vertebral disc space tissue obtained during a surgical operation or needle aspiration.

2. Patient has evidence of vertebral disc space infection seen during a surgical operation or histopathologic examination.

3. Patient has fever (≥38.8°C) with no other recognized cause or pain at the involved vertebral disc space and radiographic evidence of infection, (eg, abnormal findings on x-ray, CT scan, MRI, radionuclear scan [gallium, technetium, etc]).

CNS-CENTRAL NERVOUS SYSTEM INFECTION

IC-Intracranial infection (brain abscess, subdural or epidural infection, encephalitis)

Intracranial infection must meet at least 1 of the following criteria:

1. Patient has organisms cultured from brain tissue or dura.

2. Patient has an abscess or evidence of intracranial infection seen during a surgical operation or histopathologic examination.

3. Patient has at least 2 of the following signs or symptoms with no other recognized cause: head- ache, dizziness, fever (≥38.8°C), localizing neurologic signs, changing level of consciousness, or confusion and at least 1 of the following:
   a. organisms seen on microscopic examination of brain or abscess tissue obtained by needle aspiration or by biopsy during a surgical operation
or autopsy

b. positive antigen test on blood or urine

c. radiographic evidence of infection, (e.g., abnormal findings on ultrasound, CT scan, MRI, radionuclide brain scan, or arteriogram)

d. diagnostic single antibody titer (IgM) or 4-fold increase in paired sera (IgG) for pathogen

4. and if diagnosis is made antemortem, physician institutes appropriate antimicrobial therapy.

a. organisms seen on microscopic examination of brain or abscess tissue obtained by needle aspiration or by biopsy during a surgical operation or autopsy

b. positive antigen test on blood or urine. radiographic evidence of infection, (e.g., abnormal findings on ultrasound, CT scan, MRI, radionuclide brain scan, or arteriogram) d. diagnostic single antibody titer (IgM) or 4-fold increase in paired sera (IgG) for pathogen and if diagnosis is made antemortem, physician institutes appropriate antimicrobial therapy.

MEN-Meningitis or ventriculitis

Meningitis or ventriculitis must meet at least 1 of the following criteria:

1. Patient has organisms cultured from cerebrospinal fluid (CSF).

2. Patient has at least 1 of the following signs or symptoms with no other recognized cause: fever (.38°C), headache, stiff neck, meningeal signs, cranial nerve signs, or irritability and at least 1 of the following:

a. increased white cells, elevated protein, and/ or decreased glucose in CSF

b. organisms seen on Gram’s stain of CSF. organisms cultured from blood. positive antigen test of CSF, blood, or urine. diagnostic single antibody titer (IgM) or 4-fold increase in paired sera (IgG) for pathogen and if diagnosis is made antemortem, physician institutes appropriate antimicrobial therapy.

SA-Spinal abscess without meningitis

An abscess of the spinal epidural or subdural space, without involvement of the cerebrospinal fluid or adjacent bone structures, must meet at least 1 of the following criteria:

1. Patient has organisms cultured from abscess in the spinal epidural or subdural space.

2. Patient has an abscess in the spinal epidural or subdural space seen during a surgical operation or at autopsy or evidence of an abscess seen during a histopathologic examination.
3. Patient has at least 1 of the following signs or symptoms with no other recognized cause: fever (.388C), back pain, focal tenderness, radiculitis, paraparesis, or paraplegia, and at least 1 of the following:

a. organisms cultured from blood

b. radiographic evidence of a spinal abscess (eg, abnormal findings on myelography, ultrasound, CT scan, MRI, or other scans [gallium, technetium, etc]).

VASC-Arterial or venous infection

Arterial or venous infection must meet at least 1 of the following criteria:

1. Patient has organisms cultured from arteries or veins removed during a surgical operation and blood culture not done or no organisms cultured from blood.

2. Patient has evidence of arterial or venous infection seen during a surgical operation or histopathologic examination.

3. Patient has at least 1 of the following signs or symptoms with no other recognized cause: fever (.388C), pain, erythema, or heat at involved vascular site and more than 15 colonies cultured from intravascular cannula tip using semiquantitative culture method and blood culture not done or no organisms cultured from blood.

4. Patient has purulent drainage at involved vascular site and blood culture not done or no organisms cultured from blood.

ENDO-Endocarditis

Endocarditis of a natural or prosthetic heart valve must meet at least 1 of the following criteria:

1. Patient has organisms cultured from valve or vegetation.

2. Patient has 2 or more of the following signs or symptoms with no other recognized cause: fever (.388C), new or changing murmur, embolic phenomena, skin manifestations (ie, petechiae, splinter hemorrhages, painful subcutaneous nodules), congestive heart failure, or cardiac conduction abnormality, and at least 1 of the following:

a. organisms cultured from 2 or more blood cultures

b. organisms seen on Gram’s stain of valve when culture is negative or not done

c. valvular vegetation seen during a surgical operation or autopsy

d. positive antigen test on blood or urine (eg, H influenzae, S pneumoniae, N meningitidis, or Group B Streptococcus) and

e. evidence of new echocardiogram and vegetation seen on
CARD-Myocarditis or pericarditis

Myocarditis or pericarditis must meet at least 1 of the following criteria:

1. Patient has organisms cultured from pericardial tissue or fluid obtained by needle aspiration or during a surgical operation. 

2. Patient has at least 2 of the following signs or symptoms with no other recognized cause: fever (.388C), chest pain, paradoxical pulse, or in- creased heart size at least 1 of the following: a. abnormal EKG consistent with myocarditis or pericarditis, b. positive antigen test on blood (eg, H influenzae, S pneumoniae)

3. e. histologic examination of heart tissue shows evidence of myocarditis or pericarditis. 4-fold rise in type-specific antibody with or without isolation of virus from pharynx or feces. pericardial effusion identified by echocardiogram, CT scan, MRI, or angiography.

At least 1 of the following: a. abnormal EKG consistent with myocarditis or pericarditis, b. positive antigen test on blood (eg, H influenzae, S pneumoniae), c. evidence of myocarditis or pericarditis on histologic examination of heart tissue, d. 4-fold rise in type-specific antibody with or without isolation of virus from pharynx or feces, e. pericardial effusion identified by echocardiogram.

MED-Mediastinitis

 Mediastinitis must meet at least 1 of the following criteria:

 Patient has organisms cultured from mediastinal tissue or fluid obtained during a surgical opera- tion or needle aspiration. Patient has evidence of mediastinitis seen during a surgical operation or histopathologic examination. Patient has at least 1 of the following signs or symptoms with no other recognized cause: fever (.388C), chest pain, or sternal instability and at least 1 of the following:

 a. purulent discharge from mediastinal area

 b. organisms cultured from blood or discharge from mediastinal area

 c. mediastinal widening on x-ray.

EENT-EYE, EAR, NOSE, THROAT, OR MOUTH INFECTION

CONJ-Conjunctivitis

 Conjunctivitis must meet at least 1 of the following criteria:

 1. Patient has pathogens cultured from purulent exudate obtained from the conjunctiva or contiguous tissues, such as eyelid, cornea, meibomian glands, or lacrimal glands.

 2. Patient has pain or redness of conjunctiva or around eye at least 1 of the following:
a. WBCs and organisms seen on Gram’s stain of exudate

b. purulent exudate \(^{17}\), positive antigen test (eg, ELISA or IF for Chlamydia trachomatis, herpes simplex virus, adenovirus) on exudate or conjunctival scraping

d. multinucleated giant cells seen on microscopic examination of conjunctival exudate or scrapings

e. positive viral culture \(^{17}\)

f. diagnostic single antibody titer (IgM) or 4-fold increase in paired sera (IgG) for pathogen.

**EYE-Eye, other than conjunctivitis**

An infection of the eye, other than conjunctivitis, must meet at least 1 of the following criteria:

1. Patient has organisms cultured from anterior or posterior chamber or vitreous fluid.

2. Patient has at least 2 of the following signs or symptoms with no other recognized cause: eye pain, visual disturbance, or hypopyon \(^{17}\) and \(^{17}\) at least 1 of the following:

   a. physician diagnosis of an eye infection \(^{17}\)

   b. positive antigen test on blood (eg, H influenzae, S pneumoniae) \(^{17}\)

   c. organisms cultured from blood. \(^{17}\)

**EAR- Ear mastoid**

Ear and mastoid infections must meet at least 1 of the following criteria:

Otitis externa must meet at least 1 of the following criteria:

1. Patient has pathogens cultured from purulent drainage from ear canal. \(^{17}\)

2. Patient has at least 1 of the following signs or symptoms with no other recognized cause: fever (.388C), pain, redness, or drainage from ear canal \(^{17}\), and \(^{17}\) organisms seen on Gram’s stain of purulent drainage. \(^{17}\)

Otitis media must meet at least the following criteria:

1. Patient has organisms cultured from fluid from middle ear obtained by tympanocentesis or at surgical operation. \(^{17}\)

2. Patient has at least 2 of the following signs or symptoms with no other recognized cause: fever (.388C), pain in the eardrum, inflammation, retraction or decreased mobility of eardrum, or fluid behind eardrum. \(^{17}\)
UR-Upper respiratory tract, pharyngitis, laryngitis, epiglottitis

Upper respiratory tract infections must meet at least 1 of the following criteria:

1. Patient has at least 2 of the following signs or symptoms with no other recognized cause: fever (.388C), erythema of pharynx, sore throat, cough, hoarseness, or purulent exudate in throat and at least 1 of the following: a. organisms cultured from the specific site(s) b. organisms cultured from blood c. positive antigen test on blood or respiratory secretions d. diagnostic single antibody titer (IgM) or 4- fold increase in paired sera (IgG) for pathogen.

2. Patient has an abscess seen on direct examination, during a surgical operation, or during a histopathologic examination.

GE-Gastroenteritis

Gastroenteritis must meet at least 1 of the following criteria:

1. Patient has an acute onset of diarrhea (liquid stools for more than 12 hours) with or without vomiting or fever (.388C) and no likely noninfectious cause (eg, diagnostic tests, therapeutic regimen other than antimicrobial agents, acute exacerbation of a chronic condition, or psycho-logic stress).

2. Patient has at least 2 of the following signs or symptoms with no other recognized cause: naus, vomiting, abdominal pain, fever (.388C), or headache and at least 1 of the following:

   a. an enteric pathogen is cultured from stool or rectal swab
   b. an enteric pathogen is detected by routine or electron microscopy
   c. an enteric pathogen is detected by antigen or antibody assay on blood or feces
   d. evidence of an enteric pathogen is detected by cytopathic changes in tissue culture (toxin assay)
   e. diagnostic single antibody titer (IgM) or 4- fold increase in paired sera (IgG) for pathogen.

GIT-Gastrointestinal tract (esophagus, stomach, small and large bowel, and rectum) excluding gastroenteritis and appendicitis

Gastrointestinal tract infections, excluding gastroenteritis and appendicitis, must meet at least 1 of the following criteria:

1. Patient has an abscess or other evidence of infection seen during a surgical operation or histopathologic examination.

2. Patient has at least 2 of the following signs or symptoms with no other recognized cause and compatible with infection of the organ or tissue involved: fever (.388C), nausea, vomiting, abdominal pain, or tenderness and at least 1 of
pathogen.

**GIT-Gastrointestinal tract (esophagus, stomach, small and large bowel, and rectum) excluding gastroenteritis and appendicitis**

Gastrointestinal tract infections, excluding gastroenteritis and appendicitis, must meet at least 1 of the following criteria:

1. Patient has an abscess or other evidence of infection seen during a surgical operation or histopathologic examination.

2. Patient has at least 2 of the following signs or symptoms with no other recognized cause and compatible with infection of the organ or tissue involved: fever (.388C), nausea, vomiting, abdominal pain, or tenderness and at least 1 of the following:
   a. organisms cultured from drainage or tissue obtained during a surgical operation or endoscopy or from a surgically placed drain
   b. organisms seen on Gram’s or KOH stain or multinucleated giant cells seen on microscopic examination of drainage or tissue obtained during a surgical operation or endoscopy or from a surgically placed drain
   c. organisms cultured from blood
   d. evidence of pathologic findings on radiographic examination
   e. evidence of pathologic findings on endoscopic examination (eg, Candida esophagitis or proctitis).

**HEP-Hepatitis**

Hepatitis must meet the following criterion:

Patient has at least 2 of the following signs or symptoms with no other recognized cause: fever (.388C), anorexia, nausea, vomiting, abdominal pain, jaundice, or history of transfusion within the previous 3 months

And at least 1 of the following:

a. positive antigen or antibody test for hepatitis A, hepatitis B, hepatitis C, or delta hepatitis

b. abnormal liver function tests (eg, elevated ALT/ AST, bilirubin)

c. cytomegalovirus (CMV) detected in urine or oropharyngeal secretions.

Intraabdominal infections must meet at least 1 of the following criteria:
1. Patient has organisms cultured from purulent material from intraabdominal space obtained during a surgical operation or needle aspiration.

2. Patient has abscess or other evidence of intraabdominal infection seen during a surgical operation or histopathologic examination.

3. Patient has at least 2 of the following signs or symptoms with no other recognized cause: fever (.388C), nausea, vomiting, abdominal pain, or jaundice and at least 1 of the following:

a. organisms cultured from drainage from surgically placed drain (eg, closed suction drainage system, open drain, T-tube drain)

b. organisms seen on Gram’s stain of drainage or tissue obtained during surgical operation or needle aspiration

c. organisms cultured from blood and radiographic evidence of infection (eg, abnormal findings on ultrasound, CT scan, MRI, or radiolabel scans [gallium, technetium, etc] or on abdominal x-ray).

LRI-LOWER RESPIRATORY TRACT INFECTION, OTHER THAN PNEUMONIA

BRON-Bronchitis, tracheobronchitis, bronchiolitis, tracheitis, without evidence of pneumonia

Tracheobronchial infections must meet at least 1 of the following criteria:

1. Patient has no clinical or radiographic evidence of pneumonia and patient has at least 2 of the following signs or symptoms with no other recognized cause: fever (.388C), cough, new or increased sputum production, rhonchi, wheezing and at least 1 of the following: a. positive culture obtained by deep tracheal aspirate or bronchoscopy b. positive antigen test on respiratory secretions.

a. organisms cultured from material obtained by deep tracheal aspirate or bronchoscopy

b. positive antigen test on respiratory secretions

c. diagnostic single antibody titer (IgM) or 4-fold increase in paired sera (IgG) for pathogen.

PNEU-PNEUMONIA

There are 3 specific types of pneumonia: clinically defined pneumonia (PNU1), pneumonia with specific laboratory findings (PNU2), and pneumonia in immunocompromised patients (PNU3). Listed below are general comments applicable to all specific types of pneumonia, along with abbreviations used in the algorithms (Tables 4-7) and reporting instructions. Table 8 shows threshold values for cultured specimens used in the surveillance diagnosis of pneumonia. Figures 1 and 2 are flow
diagrams for the pneumonia algo- rithms that may be used as data collection tools.

LUNG-Other infections of the lower respiratory tract

Other infections of the lower respiratory tract must meet at least 1 of the following criteria:

1. Patient has organisms seen on smear or cultured from lung tissue or fluid, including pleural fluid.

2. Patient has a lung abscess or empyema seen during a surgical operation or histopathologic examination.

3. Patient has an abscess cavity seen on radiographic examination of lung.

Reporting instructions

d Report concurrent lower respiratory tract infection and pneumonia with the same organism(s) as PNEU.

d Report lung abscess or empyema without pneumonia as LUNG.

REPR-REPRODUCTIVE TRACT INFECTION EMET-Endometritis

Endometritis must meet at least 1 of the following criteria:

1. Patient has organisms cultured from fluid or tis- sue from endometrium obtained during surgical operation, by needle aspiration, or by brush biopsy.

2. Patient has at least 2 of the following signs or symptoms with no other recognized cause: fever, abdominal pain, uterine tenderness, or purulent drainage from uterus.

OREP-Other infections of the male or female reproductive tract (epididymis, testes, prostate, vagina, ovaries, uterus, or other deep pelvic tissues, excluding endometritis or vaginal cuff infections)

Other infections of the male or female reproductive tract must meet at least 1 of the following criteria:

1. Patient has organisms cultured from tissue or fluid from affected site.

2. Patient has an abscess or other evidence of infection of affected site seen during a surgical operation or histopathologic examination.

3. Patient has 2 of the following signs or symptoms with no other recognized cause: fever (.388C), nausea, vomiting, pain, tenderness, or dysuria and at least 1 of the following: a. organisms cultured from blood b. physician diagnosis.

d Report endometritis as EMET. d Report vaginal cuff infections as VCUF.
SST-SKIN AND SOFT TISSUE INFECTION SKIN-Skin

Skin infections must meet at least 1 of the following criteria:

1. 2. Patient has purulent drainage, pustules, vesicles, or boils. Patient has at least 2 of the following signs or symptoms with no other recognized cause: pain or tenderness, localized swelling, redness, or heat and at least 1 of the following:

   a. organisms cultured from aspirate or drainage from affected site; if organisms are normal skin flora (ie, diphtheroids [Corynebacterium spp], Bacillus [not B anthracis] spp, Propionibacterium spp, coagulase-negative staphylococci [including S epidermidis], viridans group streptococci, Aerococcus spp, Micrococcus spp), they must be a pure culture

   b. organisms cultured from blood

   c. positive antigen test performed on infected tissue or blood (eg, herpes simplex, varicella zoster, H influenzae, N meningitidis)

   d. multinucleated giant cells seen on microscopic examination of affected tissue

   e. diagnostic single antibody titer (IgM) or 4-fold increase in paired sera (IgG) for pathogen.

ST-Soft tissue (necrotizing fascitis, infectious gangrene, necrotizing cellulitis, infectious myositis, lymphadenitis, or lymphangitis)

Soft tissue infections must meet at least 1 of the following criteria:

1. Patient has organisms cultured from tissue or drainage from affected site.

2. Patient has purulent drainage at affected site.

3. Patient has an abscess or other evidence of infection seen during a surgical operation or histo pathologic examination.

4. Patient has at least 2 of the following signs or symptoms at the affected site with no other recognized cause: localized pain or tenderness, redness, swelling, or heat and at least 1 of the following: a. organisms cultured from blood b. positive antigen test performed on blood or urine (eg, H influenzae, S pneumoniae, N meningitidis, Group B Streptococcus, Candida spp) c. diagnostic single antibody titer (IgM) or 4-fold increase in paired sera (IgG) for pathogen.

DECU-Decubitus ulcer, including both superficial and deep infections

Decubitus ulcer infections must meet the following criterion:

Patient has at least 2 of the following signs or symptoms with no other recognized
cause: redness, tenderness, or swelling of decubitus wound edges and at least 1 of the following:

a. organisms cultured from properly collected fluid or tissue (see Comments)

b. organisms cultured from blood.

Comments

d Purulent drainage alone is not sufficient evidence of an infection.

d Organisms cultured from the surface of a decubitus ulcer are not sufficient evidence that the ulcer is infected. A properly collected specimen from a decubitus ulcer involves needle aspiration of fluid or biopsy of tissue from the ulcer margin.

BURN-Burn

Burn infections must meet at least 1 of the following criteria:

1. Patient has a change in burn wound appearance or character, such as rapid eschar separation, or dark brown, black, or violaceous discoloration of the eschar, or edema at wound margin and histologic examination of burn biopsy shows invasion of organisms into adjacent viable tissue. 2. Patient has a change in burn wound appearance or character, such as rapid eschar separation, or dark brown, black, or violaceous discoloration of the eschar, or edema at wound margin and at least 1 of the following:

a. organisms cultured from blood in the absence of other identifiable infection

b. isolation of herpes simplex virus, histologic identification of inclusions by light or electron microscopy, or visualization of viral particles by electron microscopy in biopsies or lesion scrapings.

3. Patient with a burn has at least 2 of the following signs or symptoms with no other recognized cause: fever (38°C) or hypothermia (36°C), hypotension, oliguria (20 cc/hr), hyperglycemia at previously tolerated level of dietary carbohydrate, or mental confusion and at least 1 of the following:

a. histologic examination of burn biopsy shows invasion of organisms into adjacent viable tissue

b. organisms cultured from blood

c. isolation of herpes simplex virus, histologic identification of inclusions by light or electron microscopy, or visualization of viral particles by electron microscopy in biopsies or lesion scrapings.

SYS-SYSTEMIC INFECTION DI-Disseminated infection

Disseminated infection is infection involving multiple organs or systems, without an apparent single site of infection, usually of viral origin, and with signs or symptoms
with no other recognized cause and compatible with infectious involvement of multiple organs or systems.

BRST-Breast abscess or mastitis

A breast abscess or mastitis must meet at least 1 of the following criteria:

1. Patient has a positive culture of affected breast tissue or fluid obtained by incision and drainage or needle aspiration.

2. Patient has a breast abscess or other evidence of infection seen during a surgical operation or histopathologic examination.

3. Patient has fever (.388C) and local inflammation of the breast and physician diagnosis of breast abscess.

General comments

1. Physician diagnosis of pneumonia alone is not an acceptable criterion for healthcare-associated pneumonia.

Although specific criteria are included for infants and children, pediatric patients may meet any of the other pneumonia specific site criteria.

Ventilator-associated pneumonia (ie, pneumonia in persons who had a device to assist or control respiration continuously through a tracheostomy or by endotracheal intubation within the 48-hour period before the onset of infection, inclusive of the weaning period) should be so designated when reporting data.

4. When assessing a patient for presence of pneumonia, it is important to distinguish between changes in clinical status due to other conditions such as myocardial infarction, pulmonary embolism, respiratory distress syndrome, atelectasis, malignancy, chronic obstructive pulmonary disease, hyaline membrane disease, bronchopulmonary dysplasia, etc. Also, care must be taken when assessing intubated patients to distinguish between tracheal colonization, upper respiratory tract infections (eg, tracheobronchitis), and early onset pneumonia. Finally, it should be recognized that it may be difficult to determine health care-associated pneumonia in the elderly, infants, and immunocompromised patients because such conditions may mask typical signs or symptoms associated with pneumonia. Alternate specific criteria for the elderly, infants and immunocompromised patients have been included in this definition of health care-associated pneumonia.

5. Health care-associated pneumonia can be characterized by its onset: early or late. Early onset pneumonia occurs during the first 4 days of hospitalization and is often caused by Moraxella catarrhalis, H influenzae, and S pneumoniae. Causative agents of late onset pneumonia are frequently gram negative bacilli or S aureus, including methicillin-resistant S aureus. Viruses (eg, influenza A and B or respiratory syncytial virus) can cause early and late onset nosocomial pneumonia, whereas yeasts, fungi, legionellae, and Pneumocystis carinii are usually pathogens of late onset pneumonia.
6. Pneumonia due to gross aspiration (for example, in the setting of intubation in the emergency room or operating room) is considered health care associated if it meets any specific criteria and was not clearly present or incubating at the time of admission to the hospital.

7. Multiple episodes of health care–associated pneumonia may occur in critically ill patients with lengthy hospital stays. When determining whether to report multiple episodes of health care–associated pneumonia in a single patient, look for evidence of resolution of the initial infection. The addition of or change in pathogen alone is not indicative of a new episode of pneumonia. The combination of new signs and symptoms and radiographic evidence or other diagnostic testing is required.

8. Positive Gram stain for bacteria and positive KOH (potassium hydroxide) mount for elastin fibers and/or fungal hyphae from appropriately collected sputum specimens are important clues that point toward the etiology of the infection. However, sputum samples are frequently contaminated with airway colonizers and therefore must be interpreted cautiously. In particular, Candida is commonly seen on stain, but infrequently causes healthcare-associated pneumonia.

1.4 Ethics Clearance Form
HUMAN RESEARCH ETHICS COMMITTEE (MEDICAL)

CLEARANCE CERTIFICATE NO. M170265

NAME: Dr Sheetal Chiba
(Principal Investigator)

DEPARTMENT: Internal Medicine
Wits Donald Gordon Medical Centre - ICU

PROJECT TITLE: Early Complications in Adult Liver Transplant Recipients at Wits Donald Gordon Medical Centre

DATE CONSIDERED: 24/02/2017

DECISION: Approved unconditionally

CONDITIONS:

SUPERVISOR: Dr Gunter Schleicher

APPROVED BY: [Signature]
Professor P Cleaton-Jones, Chairperson, HREC (Medical)

DATE OF APPROVAL: 27/02/2017

This clearance certificate is valid for 5 years from date of approval. Extension may be applied for.

DECLARATION OF INVESTIGATORS

To be completed in duplicate and ONE COPY returned to the Research Office Secretary in Room 301, Third Floor, Faculty of Health Sciences, Phillip Tobias Building, 29 Princess of Wales Terrace, Parktown, 2193, University of the Witwatersrand. I/we fully understand the conditions under which I/we am/are authorized to carry out the above-mentioned research and I/we undertake to ensure compliance with these conditions. Should any departure be contemplated, from the research protocol as approved, I/we undertake to resubmit the application to the Committee. I agree to submit a yearly progress report. The date for annual re-certification will be one year after the date of convened meeting where the study was initially reviewed. In this case, the study was initially reviewed in February and will therefore be due in the month of February each year. Unreported changes to the application may invalidate the clearance given by the HREC (Medical).

Principal Investigator Signature Date
