Applications of low-temperature crystallography

by

David Gordon Billing

A Dissertation Submitted to the Faculty of Science

University of the Witwatersrand, Johannesburg

for the Degree of Master of Science

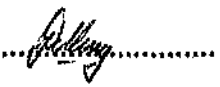

January, 1991

Abstract

Two cryostats, a liquid nitrogen gas flow cryostat and a Be walled flow cryostat, suitable for use on Enraf Nonius CAD4 four circle diffractometers have been commissioned and tested. The necessary techniques relating to crystal mounting and centring for low-temperature data collection were also developed. The complete experimental procedure was tested by determining the crystal structures of the following three compounds at low-temperatures:N-arylpyrrolidin-2-one,4-p-hydroxyphenyl-9,10,11-trihydroxy-8-ethyl-1,7-dioxaspiro[4,4]-nona-2,6-dione and 5,6-trans,-6-Bromo-5-hydroxy-3-nitrobicyclo[2.2.2]oct-2-ene. In performing these structure determinations, some of the applications of low-temperature crystallography were considered.

Declaration

I declare that this dissertation is my own, unaided work. It is being submitted for the degree of Master of Science in the University of the Witwatersrand, Johannesburg. It has not been submitted for any degree or examination in any other University.

D G Billing

January, 1991

Acknowledgements

I am grateful to my supervisor, Dr. D.C.Levendis, for his support and guidance during the course of this study.

I would also like to express my gratitude towards the following people:

Prof. J.C.A.Boeyens, for financial support in the form of a research assistantship, and the many useful discussions relating to crystallography in general.

Prof. J.P.Michael for supplying me with crystals and his interest in the work.

Prof. G.W.Perold for the excellent crystals of leucodrin and conocarpin.

List of publications

The following publications have arisen from the work presented in this thesis or from related work.

1. The structure and conformation of 1,1'-Bipyrrolidene-2,2'dithione.
   J.P.Michael, D.G.Billing, J.C.A.Boeyens, L.Carlton, L.Denner, I.Hindmarch.
   J.Mol.Struc.,238,(1990),391-401.
2. Conformational analysis of rotational barriers in N-Arylpyrrolidin-2-ones.
   D.G.Billing, J.C.A.Boeyens, L.Denner, K.du Plooy, G.C.Long, J.P.Michael.
   Acta Cryst.(B) (In Press)
3. Comparison of the NMR coupling paths in leucodrin and conocarpin by low-temperature x-ray structure analysis.
   D.G.Billing, J.C.A.Boeyens, L.Carlton, D.C.Levendis, G.W.Perold.
   J. Chem. Soc. Perkin Transactions 2 (In Press)
4. Crystallographic study of N-arylpyrrolidin-2-ones
   D.G.Billing, J.C.A.Boeyens, D.C.Levendis and J.P.Michael
   S.A.J. of Chem. (Submitted for Publication)

Work from this thesis presented as papers at conferences attended.

1. Conformational preferences in N-Arylpyrrolidin-2-ones.
   Frank Warren Conference, South Africa, April 1988.
   D.G.Billing,J.C.A.Boeyens,L.Denner and J.P.Michael.

2. Low Temperature Crystallography using a Kappa geometry diffractometer.
   SACI Convention, Johannesburg, South Africa, January 1889.

Chapter One

Introduction

When an ideally imperfect crystal is exposed to a homogeneous beam of monochromatic x-rays, a three dimensional diffraction pattern results. The spatial positions of the diffracted rays are determined by the geometric size and shape of the unit cell. The relative intensities of each of these rays on the other hand may be related to the electron density distribution contained within the unit cell. One of the first applications of x-ray diffraction was the investigation of the structure of crystals. This application was and still is of paramount importance in the fields of chemistry, physics and mineralogy, and is made possible by the Fourier relationship which exists between the distribution of the electron density within the crystal and the intensity of the x-rays diffracted by the crystal. The positions of the atoms are inferred to be at the centres of ovoids of charge. This assumption, valid for the accuracy involved in routine investigations, unfortunately leads to results which are biased.

Technical breakthroughs in recent years, such as automated diffractometry, improved cryogenics and high speed computing have increased the overall resolution attainable in the diffraction experiment, and hence have led to more precise positional parameters for the atoms in the crystals. Along with this improved resolution, the following reasons also exist as to why it would be desirable to perform the diffraction experiment at low temperatures:

1.In general the stability of crystals are improved by cooling, thus it may be possible to study crystals at low temperatures which are unstable at room temperature.

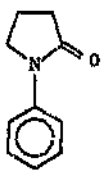

2.Compounds which are liquids at room temperature may be cooled to below their melting point, crystallised and studied.

3.Interesting phase transitions occurring below room temperatures can be studied in detail.

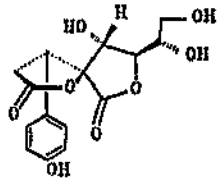

4.Disorder, frequently present in some crystals, may be resolved.

5.Total and deformation densities may be studied in detail, allowing for comparison with theoretically derived values, and investigations into the nature of chemical bonding.

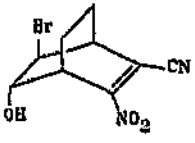

The initial aim of this project was thus to assemble and commission the necessary equipment for performing low temperature diffraction studies. During this stage of the projects, tests are also to be carried out to determine the temperature stability of the cryostats, as well as the maximum time that a crystal could be kept at a temperature of interest. Following this the techniques and methods for collecting low-temperature x-ray data have to be developed. These include methods for mounting crystals, as the normal methods used in routine x-ray diffraction studies tend to fail. Also the problem of centring a crystal in the x-ray beam when it cannot be seen had to be overcome. The complete experimental configuration was then tested by determining the low temperature structures of some compounds, in the process of doing so some of the applications of low-temperature crystallography were considered. The compounds chosen for these tests are shown below:

I

II

III

The first compound studied was N-phenyl-pyrrolidin-2-one (I). In this compound and derivatives of it, containing mono-substituted aromatic rings, the nature of the bond linking the two rings has been uncertain. A low-temperature study of this compound, conducted at a number of temperatures, allows for the effect of temperature on this bond to be evaluated. If data of a sufficiently high accuracy can be obtained, then the distribution of electronic charge in the bond can be investigated. The structures of II and III are both concerned with the determination of the positions of hydrogen atoms in molecular crystals. Hydrogen atoms have only one valence electron and no core electrons, making it difficult to locate using routine x-ray diffraction techniques. The presence of the heavy element, bromine, in III which tends to dominate the electron density distribution in such crystals, makes it even more difficult to locate hydrogen positions in such cases.

Chapter Two

The effect of temperature on the x-ray diffraction pattern of crystals[1].

Upon cooling, the diffraction pattern obtained from crystalline matter would change. The extent of the changes that would take place depends on the crystal as well as the temperature range through which the cooling takes place. A small change in temperature could lead to hardly any discernable change in the diffraction pattern, unless the crystal undergoes a phase change during the temperature change. In this case the diffraction pattern could change dramatically, depending on the nature of the phase change that takes place. Thus for example a disorder-order phase transition could result in diffuse layer lines in the diffraction pattern resolving into distinct reflections. This and other types of phase transitions could also be associated with changes in the unit cell, which on its own has a dramatic effect on the spatial distribution of reflections.

On the other hand if a crystal does not undergo a phase change on cooling the changes in the diffraction pattern are more subtle, even for large changes in temperature. Firstly the unit cell of the crystal will undergo a slight reduction in size due to thermal contraction. This would cause a slight spreading out of the reflections in the diffraction pattern.The intensity,I, of a diffracted reflection is related to the structure factor by the following

[1]The material for this chapter was summarised from similar work contained in the books listed in the bibliography.

expression:

$$F=\sqrt{\frac{KI}{Lp}}$$

where p, the polarisation factor, describing the polarisation which takes place in the primary beam because of the monochromator, is given by

$$p=(1+\cos^2 2\theta)/2$$

where θ is the angle of diffraction.

The Lorentz factor L, is dependant on the precise measurement technique used. While K represents a scaling factor dependent on effects such as crystal size and primary beam intensity. We thus have that

$$F\propto\sqrt{I}$$

The effect of cooling on the intensities of individual reflections is now most readily seen by considering the structure factor expression:

$$F(h)=\sum_{j=1}^{N} f_j e^{2\pi i \mathbf{h}\mathbf{r}_j}$$

where F(h) is the structure factor associated with the reciprocal space vector h, f denotes the atomic scattering factor for atom j, having position vector r. This expression is only valid for molecules at rest, as the scattering factors used, f_j, correspond to a stationary atom model. The scattering factors cause the inherent intensity decrease with respect to $\sin\theta/\lambda$ depicted in figure 2.1.

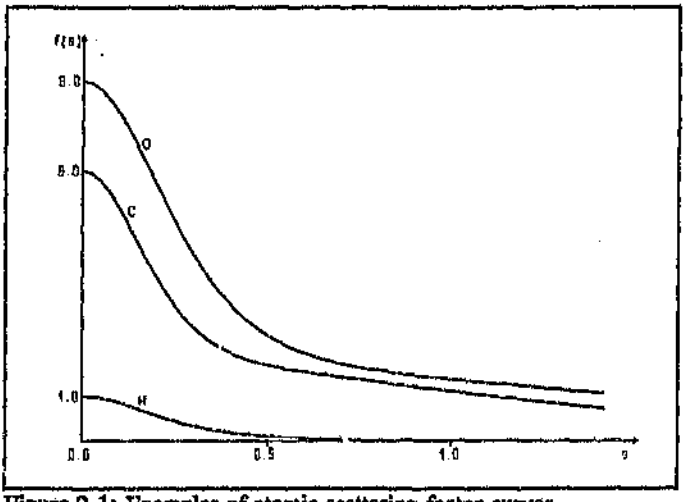

Figure 2.1: Examples of atomic scattering factor curves.

The thermal motion of an atom can be taken into account if the scattering factor for the stationary atom is replaced by the scattering factor for a vibrating atom, f_t which has the form:

$$f_t = f_0 e^{(-B\sin^2\theta)/\lambda^2}$$

The quantity B, known as the Debye-Waller factor is related to the atomic vibration by:

$$B = 8\pi^2 u^2 = 8\pi^2 U$$

where u is the root-mean-square amplitude of atomic vibration, U is the temperature factor generally refined. The effect of the additional term in the structure factor expression, is to cause an increased fall-of of intensity with respect to $\sin\theta/\lambda$, as is shown in figure 2.2 for various values of B.

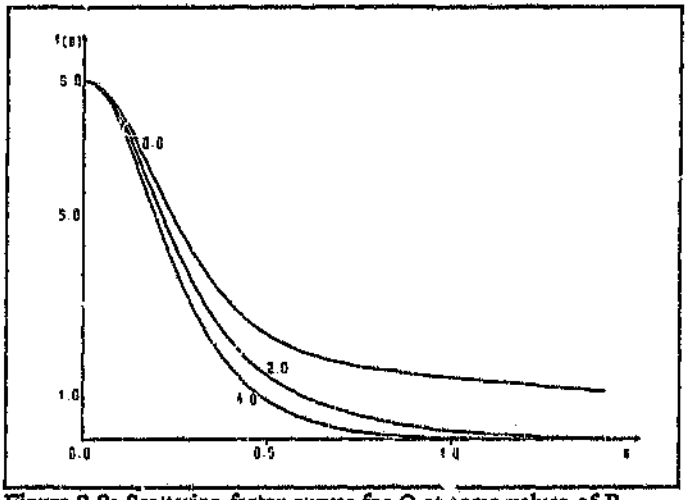

Figure 2.2: Scattering factor curves for O at some values of B

Thus on cooling, the high order reflections show the most obvious change in that they become more intense. More importantly, they become measurable. Thus the number of measured reflections included in a data set increases. This results in better, more precise structure refinements, including lower R-factors. Lower temperatures also improve the precision of the diffraction experiment. This is because intrinsic curvature of the electron density is increased and the magnitude of the thermal diffuse scattering is reduced, allowing for more accurate measurement of reflection intensities.

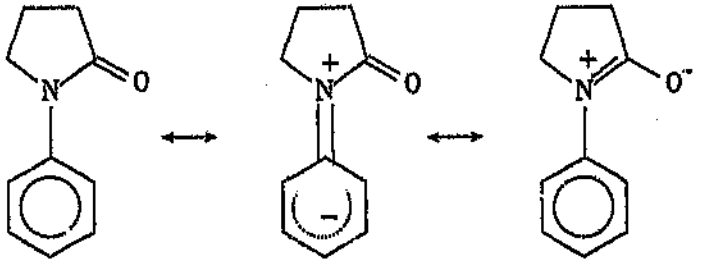

Thus for a crystal that does not undergo a phase transition, the most striking change in its x-ray diffraction pattern on cooling is the large increase in the number of observable reflections. On closer inspection each of the reflections will also be found to have become sharper, due to the reduction of the thermal motion within the crystal. This results in more precise structure determinations with significantly smaller standard deviations associated with the various structural parameters.

Chapter Three

The crystal structure of N-phenylpyrrolidin-2-one at selected low temperatures.

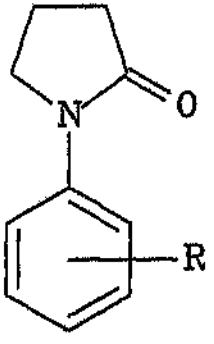

3.1 Introduction

In molecules such as mono-substituted N-arylpyrrolidin-2-ones (eg. I to VIII), restricted rotation around the inter-ring bond could arise from resonance involving the carbonyl group, the nitrogen lone pair and the aromatic system:

Under this scheme the occurrence of the barrier should be accompanied by shorter N-C(Ar) and N-C(O) bonds, a longer C-O distance and a planar system.

The group of related structures I to VIII formed the basis for investigating the barrier to rotation, and the effect of different substituents on such a barrier, both electronically and sterically in mono-substituted N-phenylpyrroldin-2-ones.

I : R=H

II : R=*o*-CH_3

III : R=*m*-CH_3

IV : R=*p*-CH_3

V : R=*m*-OCH_3

VI : R=*p*-OCH_3

VII : R=*m*-NO_2

VIII : R=*o*-OH

By performing the study at various low temperatures in the range of 90K to room temperature, the possible effects of temperature on the solid state conformation of the molecule could possibly be assessed. For the purposes of such a study, compound I was chosen due to its crystal quality, relative high symmetry and availability. It was also hoped that data of a sufficiently high quality could be obtained to allow for a study of the electron density distribution around the central bond. This would hopefully lead to a better understanding of the conformational preferences exhibited by this series of molecules.

3.2 Experimental

Good quality near cubic crystals, grown from CCl_4 across a hexane interface, with edges approximately 0.5mm in size were selected for study. Data were collected on Enraf Nonius CAD4 diffractometers, equipped with graphite single-crystal monochromators, using the cryostats described in chapter 6. Cell constants were obtained from least-squares refinement of 25 high angle θ values. Data reduction

consisted of correction for background, decay (linear), Lorentz and polarisation effects. Table 3.1 contains the crystallographic data at the various temperatures. The structures were solved by direct methods and refined using full matrix least-squares techniques, with the SHELX set of programs.[Sheldrick, 1985]. Table 3.2 contains the fractional coordinates of the 160K structure, which at present is the most precise determination of this structure. Figure 3.1 shows an Ortep diagram of the structure as well as the numbering scheme used throughout this series of structures. The coordinates of the other structures, as well as tables containing bond lengths and bond angles are included in appendix 1. Tables of thermal parameters and structure factors are included as supplementary material on microfiche.

3.3 Discussion

Crystallographic studies of the structures, of compounds of the type presently under consideration, have resulted in the bond length and bond angle information given in Tables 3.3 and 3.4, for different substituents (R) on the phenyl rings. From this data it would appear that the central bond between the two rings (N-C5) remains effectively constant in length, (average = 1.419 Å), independent of the torsion angle between the two rings. Further, from molecular mechanics studies a rotational barrier of 7kJmol^{-1} [Billing, Boeyens, Denner, du Plooy, Long and Michael, 1990] has been inferred to exist around the bond.

Table 3.3:Selected bond lengths for related substituted compounds.

	R	Bond Length/Å

Table 3.5: Selected bond lengths and angles for n-phenylpyrrolidin-2-one at various low temperatures.

	Bond length	Torsion angles/°		Angle between
T/K	N-C5	C1-N-C5-C6	C1-N-C5-C10	mean planes/°
R.T	1.404(4)	34.9(2)	-147.4(4)	33.6(1)
160	1.415(2)	35.6(1)	-146.4(2)	34.23(6)
100	1.406(3)	36.1(2)	-145.6(3)	35.2(1)
90	1.421(4)	35.8(2)	-145.7(4)	24.5(2)

It would thus appear as if this barrier to rotation can be ascribed to either packing interactions or to nuclear screening [Boeyens, 1982]. Table 3.5 lists the values obtained for the N-C5 bond length at the different temperatures as well as some of the torsion angles for n-phenylpyrrolidin-2-one. From this table it is clear that the conformation of the molecule does not change with temperature. This can also be seen from figures 3.2 and 3.3, which show stereo projections of the structure at 90K and room temperature respectively. This would seem to suggest that the barrier to rotation does not exist due to packing interactions. Further evidence of this is the success of the molecular mechanics calculations in reproducing the crystal structures. Attributing the barrier to nuclear screening, compels one to consider the distribution of electronic charge throughout the molecule. Now although low-temperature crystallography as a technique is eminently suited to such a task, it is not feasible in the present case. This is because of the deterioration of the crystal quality on cooling which makes it impossible to collect a sufficiently large and accurate data set for performing electron density studies.

Chapter Four.

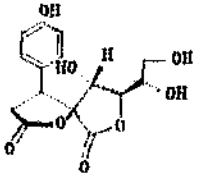

The low temperature structure of Leucodrin

4.1 Introduction

Leucodrin (I) is obtained from *leucacendron salignum* (ex *adscendens*) [Perold and Pachler, 1966] a species of the Protacean family. Its stereochemistry was demonstrated by X-ray analysis of the dibromo derivative [Diamand and Rogers, 1964], for which no coordinates were reported. The diastereomer of leucodrin, conocarpin (II) comes from *leucospermum conocarpodendron* (L) Buek. [Kruger and Perold, 1970] also of the Protaceae family.

I

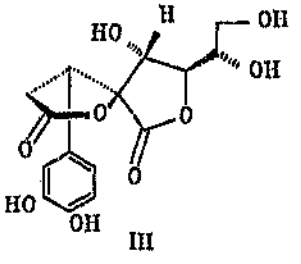

II

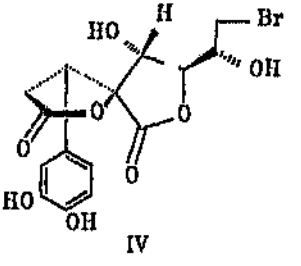

An NMR study of leucodrin[1] and conocarpin revealed five-bond proton-proton couplings of the order of 1 Hz for leucodrin, whilst the corresponding value for conocarpin is reduced to 0.4 Hz. It is of interest to note that three congeners of leucodrin, viz. leudrin (III), its 11-bromo-11-deoxy derivative (IV) and its *ar*-dimethyl ether (V) also show five-bond proton-proton couplings of the order of 1 Hz, over the

[1] IUPAC: 4-p-hydroxyphenyl-9,10,11-trihydroxy-8-ethyl-1,7-dioxaspiro[4,4]-nona-2,6-dione. The detailed numbering is shown in VI

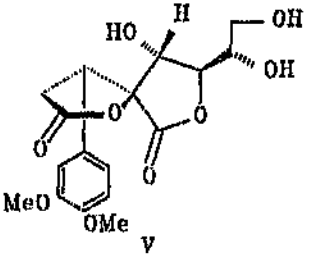

same six atom chain: 3a-H,3-C,4-C,5-C,9-C,9-H [Perold, Carlton, Howard and Michael, 1988]. An interesting aspect of this coupling is that no coupling is evident for the similar chain starting with the 3b-H atom.

V

VI

In order to rationalise this clearly observable $^{5}J_{3\text{-}H,9\text{-}H}$ coupling in the NMR spectra of leucodrin and conocarpin, it is necessary to consider the relative co-planarity of the six atoms involved in terms of the detailed geometry of the molecules. In this respect the positional parameters derived for hydrogen atoms from routine x-ray structure determinations are possibly not sufficiently precise. Thus the structure of leucodrin was determined by x-ray diffraction methods at ambient temperature and at 100K. From this study it is hoped that observed coupling may be rationalised. Furthermore by comparing the two structures the reliability of the hydrogen positions in the room temperature structure of conocarpin can be inferred. This became necessary because conocarpin crystals shattered on cooling.

4.2 Experimental

Crystals of good quality were obtained from Prof. G.W. Perold, and used for the data collection using an Enraf-Nonius CAD4 diffractometer, equipped with an incident beam graphite crystal monochromator. For the low temperature data the gas flow croystat described in chapter 6 was also used. Cell constants were determined by least-squares refinement based on the optimised setting angles of 25 high θ reflections, each measured at four positions. Data reduction consisted of correction for background, Lorentz and polarisation effects. In each case three standard reflections were also monitored hourly, but these only showed random fluctuations. The structures were solved by direct methods and refined by full-matrix least-squares using the SHELX set of programs. [Sheldrick, 1985]. In the room temperature structure all the hydrogen atoms were placed in geometrically calculated positions with a refined common U_{iso}(=0.060(4)). In the low temperature structure the hydrogen atom positions were located from difference Fourier maps and refined with a common refined U_{iso}(=0.016(1)). Although the absolute structure could not be refined with confidence, the known stereochemistry [Diamand and Rogers, 1964] gave a slightly better numerical fit with the numerical data in each case. Crystal and diffraction data are contained in tables 4.1 and 4.2, whilst refined atomic coordinates are collated in tables 4.3 to 4.5. Labelled Ortep drawings of the molecules are shown in figures 4.1 to 4.3. Tables of bond lengths and bond angles are included in appendix 2. Structure factors and anisotropic thermal parameters are included as supplementary material on microfiche.

4.3 Discussion

In the current study it is of interest to compare the two structures obtained or Leucodrin. This is most readily achieved by overlaying transparencies of the structural diagrams of figures 4.1 and 4.2. The overlay is almost exact, with the obvious differences being in the hydrogen positions of the hydroxyl groups. The experimental average O-H bond length of 0.73(1)Å is significantly shorter than the 1.08Å assumed in the geometrical calculations involved when positioning the hydrogens in the ambient temperature structure. Similarly the observed C-O-H angles, an average 107(1)°, are less than the 114° assumed for the geometrical calculation. The causes for these differences are many, but the most significant must be the use of spherical scattering factors for H, even though the electron density cloud of the hydrogen atom would be heavily distorted. Also important is the use of 1.08Å by the refinement program for the geometrical calculation. This is the bond length of C-H obtained by neutron diffraction, the equivalent O-H distance being 0.967Å [Allen, Kennard, Watson, Brummer and Orpen, 1987]. The calculated hydrogen positions seem far more reliable however when looking at C-H bonds and angles. The observed average of 0.997Å compares quite favourably with the 1.08Å assumed, The calculated hydrogen atom positions with respect to the five-bond couplings of interest, from C3 to C9 are therefore not in doubt.

Because of the presence of several hydroxyl and carbonyl groups in these molecules a variety of intermolecular hydrogen bonds is expected in the solid state. Several such possibilities are observed, but only in the case of the low-temperature leucodrin structure has any attempt been made to identify hydrogen bonds in terms of non-bonded

intermolecular O···H contacts. The only contact of less than 2Å, between O21···H20 (d=1.75Å) can be so interpreted with confidence. Other possibilities are presented by the contacts d(O20···H23)=2.00Å, d(O19···H22)=2.07Å.

Cases of 5-bond proton-proton coupling over single bonds are rare. It is therefore of interest to note that three congeners of leucodrin, showed five-bond coupling, of the order of 1 Hz over the six atom chain; 3a-H,3-C,4-C,5-C,9-C,9-H in solution, while no such effect is observable for the similar chain starting with 3b-H. [Perold, Carlton, Howard and Michael, 1988]. This effect has now also been established for leucodrin itself, as well as for Conocarpin. Long range couplings of this order are generally rationalised in terms of a planar disposition of the atoms, the so-called W-coupling mechanism or possibly using a through space effect. In the case of leucodrin it was found that the relative planarity of the chain does not distinguish between the two cases, table 4.6. Similarly the linear separation, table 4.6, between 3-H and 9-H does not offer any specific rationale for the coupling effects observed. The differences in the linear separation between leucodrin and conocarpin merely indicate conformational differences between the two molecules, as can be seen from the stereo diagrams of figures 4.4 and 4.5. At this stage one now considers coupling interactions over single bonds to occur via the bonding electrons, and that vicinal orbital transmissions are at a maximum when these orbitals are trans to each other. Then, for a six atom system three torsion angles of 180° along a planar array would offer the most favourable coupling condition. In the case of leucodrin and conocarpin the three torsion angles in the chain 3-H to 9-H are given in table 4.7. In the case of the chain 3b-H to 9-H for leucodrin the first torsion angle (at -94°) indicates that the first σ-orbital is orthoganally aligned to the plane of

the other two orbitals, hence minimal coupling is expected, as is found table 4.8. Similar reasoning can also be applied in the case of conocarpin, however here one should note that the second torsion angle in the series is also close to orthogonal. From this one can only conclude that whereas an orthogonal torsion angle at the terminus of a six atom chain minimises coupling, its location midway along the chain has a far lesser effect.

Chapter Five

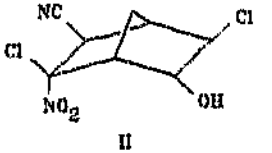

Hydrogen positions in the presence of Bromine.

5.1 Introduction.

Previous studies of norbornyl type systems, containing nitro and hydroxy side chains, have shown that the possibility of forming intramolecular hydrogen bonds in such systems is of interest.The presence of bromine, or other heavy elements, in a crystal tends to make it difficult to locate hydrogen atom positions. This was the case in the determination of the structure of I [Blom, Edwards, Field and Michael, 1980]. A method around this problem was put forward by Boeyens, Denner and Michael (1984), when they determined the structure of II. Their method involves the replacement of the bromine atoms, by chlorine which is far lighter. The method then hinges on the assumption that the two structures are identical.

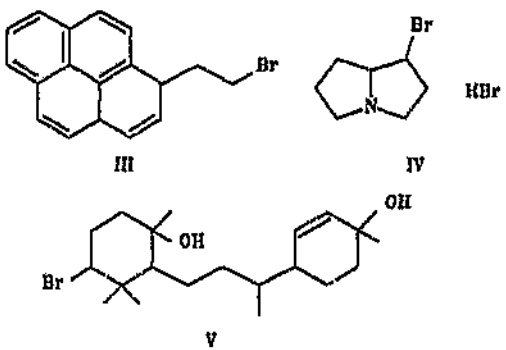

I

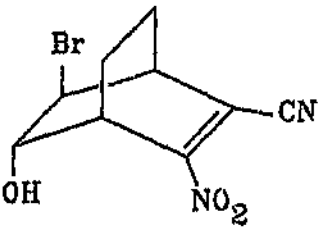

II

The method of choice for determining hydrogen positions in crystals is without doubt neutron diffraction. Facilities for using this method are however not readily available, hence the search for alternatives. Locating hydrogen positions using low temperature x-ray data seems possible considering that the hydrogen atoms were located and refined isotropically for III [Foss and Stevens, 1985], IV [Wilson and Sawicki, 1979] and V [Schmitz, Hollenbeak, Carter, Hossain and van der Helm, 1979].

While testing the cryostats, we decided to see if, by lowering the temperature at which the experiment is done, hydrogen atom positions could be determined, and possibly be refined in the presence of bromine atoms. For the purposes of our investigation suitable crystals of VI (IUPAC: 5,6-trans,-6-Bromo-5-hydroxy-3-nitrobicyclo[2.2.2]oct-2-ene-carbonitrile) were obtained from Prof. J.P Michael. This compound is sufficiently similar to those studied previously to allow for a consideration of the method, even though no intramolecular hydrogen bonding is expected in this case.

VI

5.2 Experimental

Using the crystals obtained from J.P.Michael, data were collected on a Nonius CAD4 single crystal diffractometer using graphite monochromated Mo-Kα radiation. For the 100K data the gas flow cryostat described in chapter seven was again used. Cell parameters were determined using four equivalents each of 25 high θ reflections. Crystal decay was monitored using three standard reflections, remeasured after each hour of exposure, but showed only random fluctuations. Data reduction consisted of corrections for background, Lorentz, polarisation and absorption, the latter empirically (North, Phillips and Mathews, 1968). The structures were solved by direct methods and refined with full-matrix least-squares techniques using the SHELX set of programs. For the ambient temperature structure no hydrogen atoms could reliably be located from difference Fourier maps, and hence all were placed in geometrically calculated positions (C-H 1.08Å), with a common refined isotropic temperature factor. For the 100K structure all hydrogen atoms were located, and their positions refined, again with a

common refined isotropic temperature factor. Crystal and diffraction data for the structures are contained in table 5.1. Fractional atomic coordinates are given in tables 5.2 and 5.3. The numbering scheme used is shown in the Ortep drawings in figures 5.1 and 5.2. Tables containing bond lengths and angles are included in the appendix 3. Anisotropic thermal parameters and tables of observed and calculated structures factors are included as suplementary material on microfiche.

5.3 Discussion

By determining the structure of VI at ambient temperature and at 100K, and keeping all other experimental conditions as nearly identical as possible it was possible to show that by reducing the thermal motion of the atoms in the crystal, the determination of hydrogen positions in the presence of heavy elements becomes feasible. The results are somewhat detracted from by the large residual electron density and the elongated thermal ellipsoids. These effect are almost certainly due to absorption, or other effects relating to the large crystal used. In this case the optimum crystal thickness, given by $t_{opt}=2/\mu$,where μ is the linear absorption coefficient of the crystal, would be about 0.5mm. The crystal is thus almost twice the optimum size based on absorption effects alone. More importantly though, for a crystal of this size it is quite possible that the whole of it is not exposed to a homogeneous beam. This could introduce systematic errors into the data that cannot be corrected for. It can only be hoped that since the

structural parameters seem reasonable the systematic errors introduced in this manner, were not too severe.

When comparing the two structures of VI, shown in stereographic projection in figures 5.3 and 5.4, it is apparent that the hydroxyl hydrogen position is different for the two structures. On closer inspection it is evident that there are differences in the positions of the other hydrogens as well. This is most likely due to the manner in which the hydrogen positions are determined for the ambient temperature structure. That is, they were placed in geometrically calculated positions. This procedure tends to work well for hydrogen atoms attached to carbon, but generally fails when dealing with hydrogens attached to other elements. The reason for this is that only the geometries associated with carbon are provided for by the refinement program.

Chapter Six

Experimental, equipment and techniques.

6.1 Introduction

Essentially the cryostats used in low temperature x-ray diffraction experiments may be divided into two categories, depending on the cryogen used. For liquid helium the cryostat can be based on a liquid flow cryostat or it can incorporate a closed cycle helium refrigerator. The latter having the advantage of allowing for long term data collections. Liquid helium cryostats require that the crystal under study be enclosed in the cryostat, generally using Be windows, to reduce thermal losses. Liquid nitrogen cryostats on the other hand are generally of the continuous gas flow type. In this case a stream of cold nitrogen gas is used to cool the crystal to the desired temperature, typically in the range 100K to 273K.

In this project two cryostats, a liquid helium flow cryostat and a nitrogen gas flow cryostat, designed and manufactured by Enraf Nonius, were assembled, commissioned and tested. The Helium cryostat was further modified to allow it to operate using liquid nitrogen as cryogen as well.

Although an operational cryostat would be the first step to performing a low temperature diffraction experiment, a number of other factors also need to be taken into

consideration to fully exploit the capabilities of the technique. The most important among these would be the alignment of the diffractometer as well as the centring of the crystal within the x-ray beam.

6.2 CAD4 alignment.

After aligning the diffractometer a few times according to the method set out in the operators manual, it was found that the method could be improved by slight modification.

For the alignment, the CAD4 routine ALIGN and a suitable crystal, ie. a good, stable diffractor free of absorption problems is required. For the routine ALIGN at least one reflection with $80 \leq \chi \leq 100$ (eulerian diffractometer angles are defined in figure 6.1) is required in the reflection list. (two or more reflections give more consistent results). These reflections have to be found and centred before invoking ALIGN, which would then accurately measure the positions of the eight equivalents of the selected reflection. From this the errors in the alignment are calculated and corrected for as set out in table 6.1 using the adjusters indicated in figures 6.2 and 6.3. Note that the vertical may be adjusted in one of two places, indicated as a course and a fine adjustment. Generally it should only be necessary to use the course adjustment, the fine adjustment being more intimately linked with the monochromator. During the final stages of alignment or when a very accurate alignment is desired, the centring of the crystal in the x-ray beam will become crucial, and should also be corrected for according to the coordinate axis set out in figure 6.4.

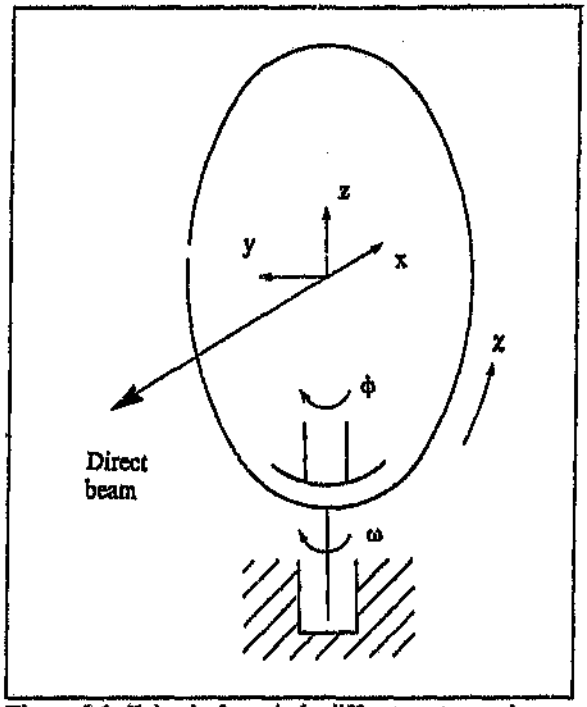

Figure 6.1: Eulerain four circle diffractometer angles.

6.3 Operation of the LN_2 gas flow cryostat

The cryostat when assembled as shown in figure 6.5, cools the crystal by boiling of nitrogen and then blowing it over the crystal. In this, condensation and icing can be a problem. Icing on the goniometer head is minimised by surrounding the cold stream with a concentric warm one. To get around all the other possible condensation problems it is necessary to seal the CAD4 enclosure and to then dry the inside atmosphere to below 30% relative humidity. This is most readily accomplished by the use of silica gel.For the best temperature stability it is important that the level of liquid nitrogen in the transfer dewar be kept as constant as possible. This is done by regular refills from a large (100l) supply dewar. It is vitally important that the level sensors in the transfer dewar are in proper working order. Finally by stepping through reciprocal space in a different pattern ice formation could also by limited and the quality of the data improved.

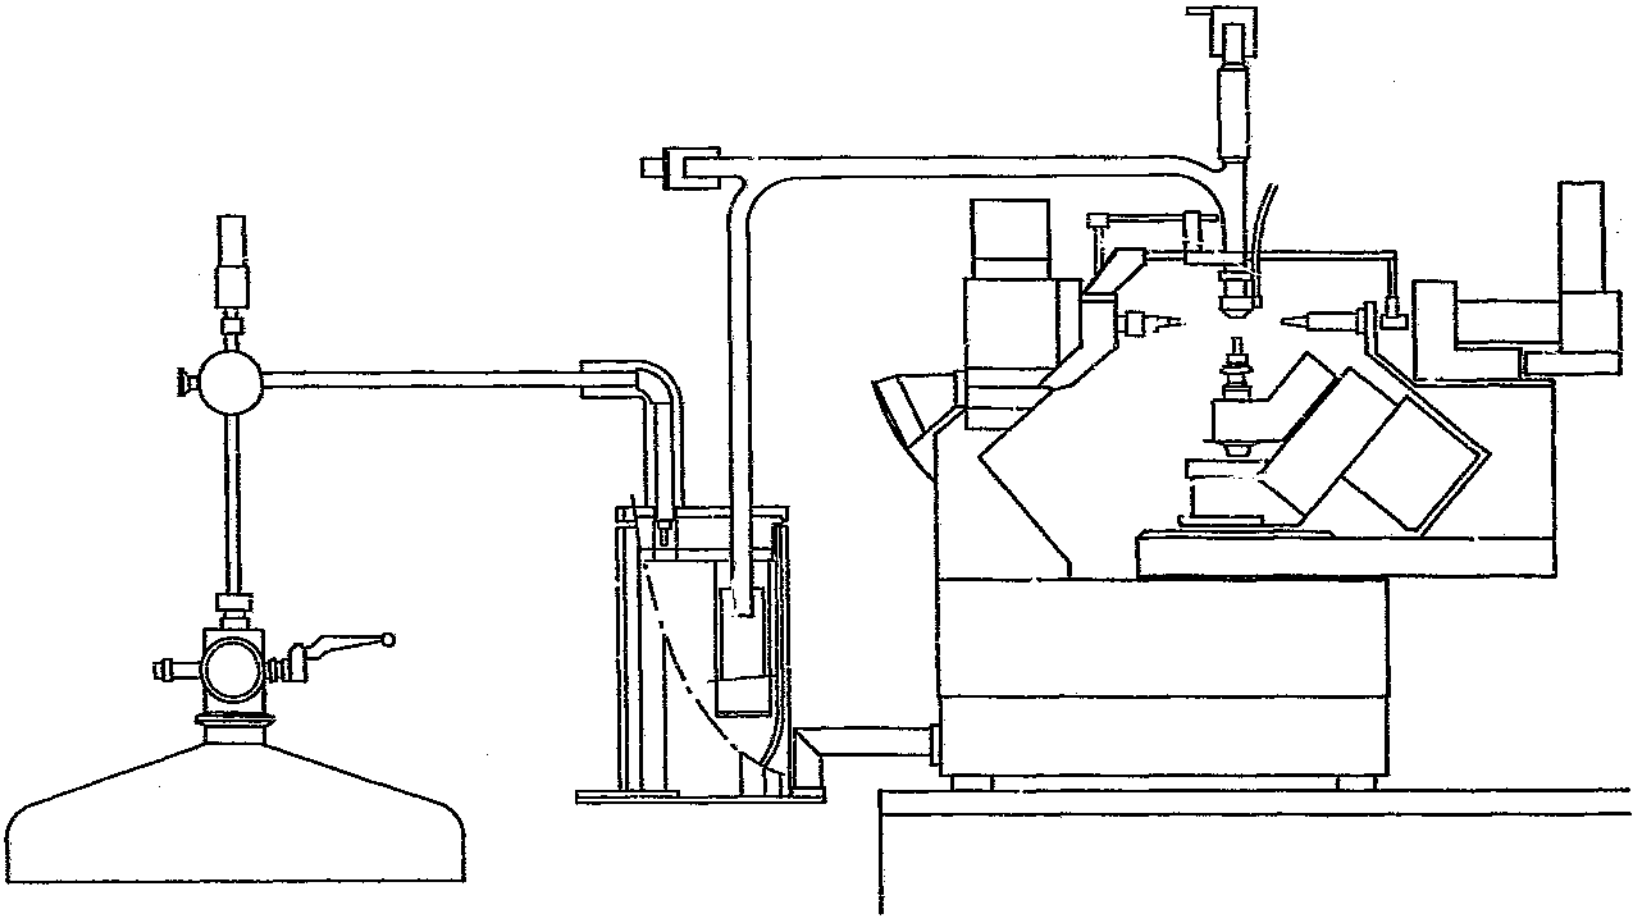

Figure 6.5: Assembled gas flow cryostat.

6.4 Operation of the Be walled flow cryostat.

The flow cryostat cools the crystal by keeping it in a cold chamber, to which a heat exchanger is attached. Coolant is then allowed to pass through the heat exchanger. The beryllium walled cryostat, when assembled as in figure 6.6, may be used with either liquid helium or with liquid nitrogen acting as cryogen. It is important to note that when using liquid nitrogen as cryogen the diffusion pump should be on for the duration of the experiment, so as to provide sufficiently good insulating vacuum. This is not necessary when using liquid helium as it operates as a cryo-pump, thus producing its own insulating vacuum.

The crystal is mounted on an insulating cup, as shown in figure 6.7, the one supplied with the cryostat, is double walled, with a vacuum in between the walls. This provides excellent insulation between the cold chamber and the goniometer. When a cup with inferior insulating properties is used then condensation is likely to occur on the goniometer head and possibly on the outside of the cryostat. At 15K the cryostat consumes approximately 30 litres of liquid helium per day. Because of the higher heat capacity of liquid nitrogen the cryostat is far more efficient when it is used. In the latter case the minimum temperature attainable is approximately 90K.

Compared to the gas flow cryostat, where a lot of scope for variations exists, the flow cryostat requires a far more detailed and rigid routine to successfully mount and operate it. In this respect the following procedure was found to work and is thus recommended.

1.Set software and hardware limits

2.Mount crystal on CAD4

3.Centre the crystal optically.

4.Get an orientations matrix (by searching for reflections and then indexing those found).

5.Mount the cryostat.

6.Check the orientation matrix. This is in case the crystal got knocked off the mount whilst mounting the cryostat. The quality of the cell would have deteriorated somewhat due to the absorption of the x-rays by the beryllium windows of the cryostat.

7.Purge the cold chamber with high purity helium.

8.Again check the orientation matrix.

9.Start cooling down by switching on the pump and opening the necessary valves. While cooling down follow the orientation matrix by reentering the reflections used for its determination. This is useful as the crystal will most definitely move during this stage of the experiment.

10.When the temperature has stabilised recentre the crystal using the four equivalents as set out in the next section.

11.When the crystal has been centered, data collection may proceed as normal.

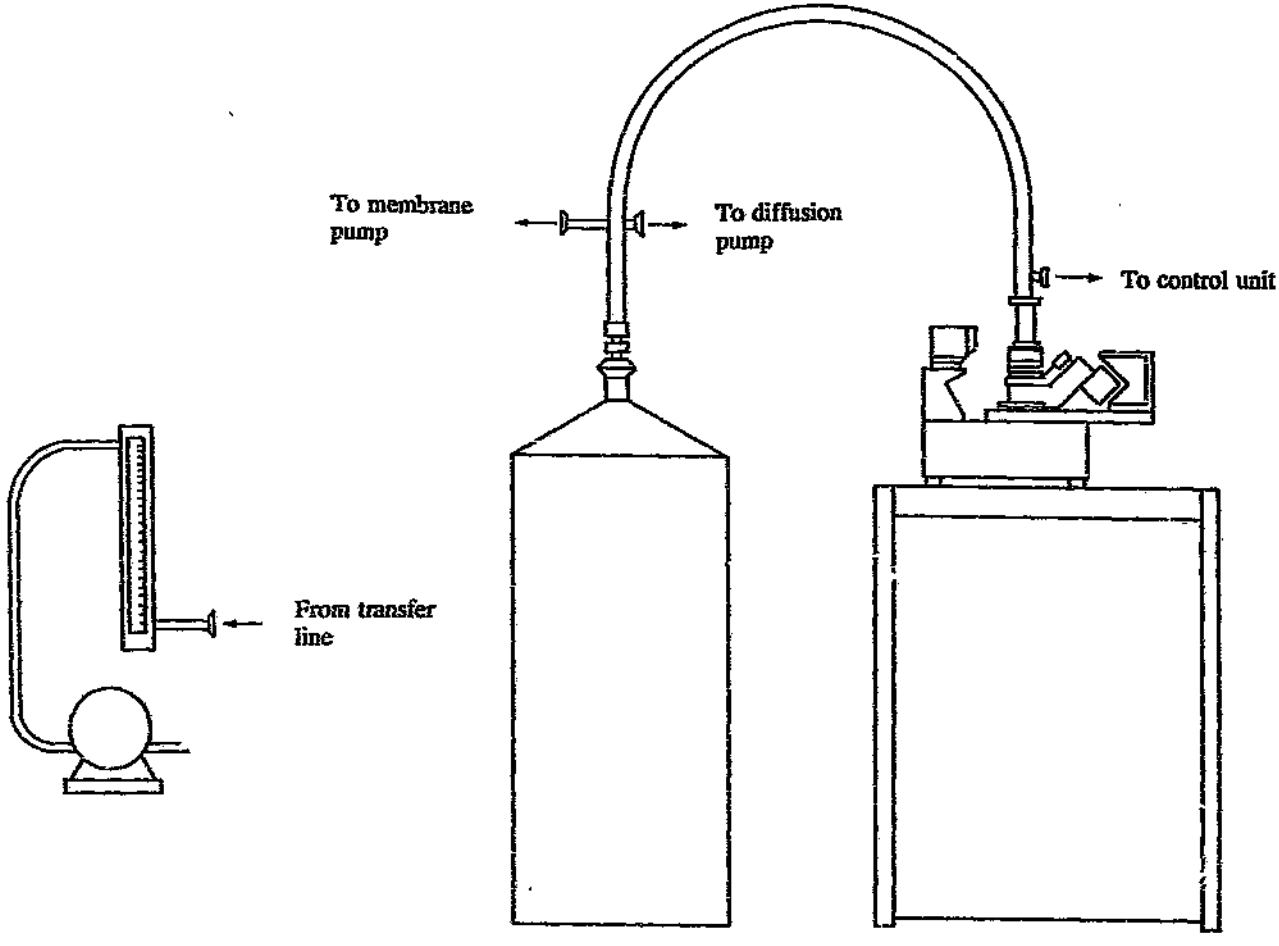

Figure 6.6: Assembled Be-walled flow cryostat.

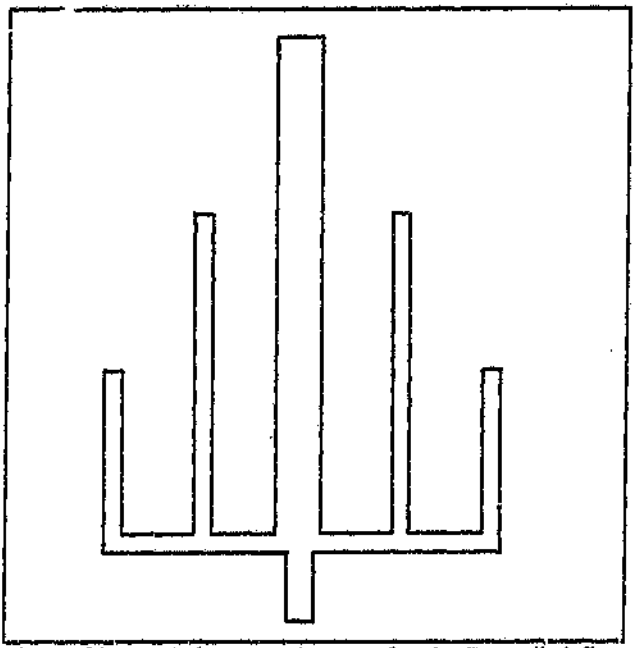

Figure 6.7: Insulating mounting cup for the Be walled flow cryostat.

6.5 Centring

As has been mentioned previously, accurately centring the crystal is very important when intending to collect an accurate data set. The desired centring precision is often greater than can be obtained optically when using a telescope. Furthermore with some experimental configurations it is not possible to see the crystal. Hence it is necessary to centre the crystal by using the equivalent reflections, of which there are eight on a four-circle diffractometer. When the motion of the goniometer is not restricted, then all eight of these equivalents are accessible and the crystal may be centred using the routine 'ALIGN' in the same manner as when aligning the diffractometer. However when the Beryllium-walled flow cryostat is mounted on the goniometer, the motion of the Kappa

arm necessarily becomes restricted to $-60° \leq K \leq 60°$. Thus making it impossible to reach high χ values. The resultant of this is that only four of the eight settings listed in table 6.2 [Ibers and James, 1974] are accessible.

Table 6.2:Eulerian angles for the eight equivalent settings accessible on a four circle diffractometer.				
Indices				
hkl	ϕ	χ	2θ	ω
-h-k-l	$\pi+\phi$	$-\chi$	2θ	ω
hkl	ϕ	χ	-2θ	$-\omega$
-h-k-l	$\pi+\phi$	$-\chi$	-2θ	$-\omega$
hkl	$\pi+\phi$	$-\chi$	2θ	$-\omega$
-h-k-l	ϕ	χ	2θ	$-\omega$
hkl	$\pi+\phi$	$-\chi$	-2θ	ω
-h-k-l	ϕ	χ	-2θ	ω

Table 6.3:Observed χ and 2θ values for the accessible settings.			
Setting	Indices	Observed χ	Observed 2θ
1	hkl	$\chi+\chi_o+\Delta\chi_{zl}+\Delta\chi_c$	$2\theta+2\theta_o+S_x-S_y+C_x+C_y$
2	-h-k-l	$-\chi+\chi_o+\Delta\chi_{zl}+\Delta\chi_c$	$2\theta+2\theta_o-S_x+S_y-C_x-C_y$
3	hkl	$-\chi+\chi_o-\Delta\chi_{zl}-\Delta\chi_c$	$-2\theta+2\theta_o+S_x+S_y+C_x-C_y$
4	-h-k-l	$\chi+\chi_o-\Delta\chi_{zl}-\Delta\chi_c$	$-2\theta+2\theta_o-S_x-S_y-C_x+C_y$

The various terms added to and subtracted from χ and 2θ to get the observed values listed in table 6.3, come from the different errors that are caused by a badly centred

crystal. From the observed χ values the following expression was derived, during this project, for Δz, the error in the vertical height of the crystal.

$$\Delta z = \left[4\chi_m - \frac{\Delta h}{2R_c \sin\theta}\right]\left(\frac{2\sin\theta}{\left[\frac{1}{R_s}+\frac{1}{R_c}\right]}\right)$$

where Δh = Error in detector height

R_c = Crystal to counter distance

R_s = Crystal to source distance

$\chi_m = \chi_1+\chi_2-\chi_3-\chi_4$, χ_i is the observed χ value for setting 1.

Similarly the errors Δx and Δy in the diffraction plane may be derived from the observed values of 2θ, resulting in the following relationships.

$$\Delta x = \frac{\theta_x}{4\sin\theta\left[\frac{1}{R_s}+\frac{1}{R_c}\right]}$$

$$\Delta y = \frac{\theta_y}{4\cos\theta\left[\frac{1}{R_s}-\frac{1}{R_c}\right]}$$

where $\theta_x = \theta_1-\theta_2+\theta_3-\theta_4$

$\theta_y = \theta_2+\theta_3-\theta_1-\theta_4$, θ_i is the observed 2θ value for setting 1.

Thus for a well aligned diffractometer, the crystal may be centred using information from only four settings of the equivalents. These ideas have been incorporated into a

FORTRAN program CENTRE, a listing of which is included in the appendix.

6.6 Crystal mounting

The seemingly simple operation for routine work is often the cause of great frustration when it comes to low-temperature studies. This is because a contraction of the mount as well as changes in the properties of the adhesive used can take place. Contraction generally leads to the crystal moving away from the centre of the x-ray beam. This is readily corrected for by reentering the crystal when the temperature has stabilised. The adhesive used can cause more severe problems as some crack on cooling to a very low temperature. This could lead to the crystal falling of the mount or to it being damaged as well. High vacuum grease was found to be the most effective for attaching a crystal to a glass fibre. Mounting crystals in capillaries is not recommended, as the capillary still introduces absorption effects noticeable in high resolution studies, it may require elaborate correction of the data, as is done by the program of De Titta (). Also the crystal is often damaged when it is inserted into the capillary.

6.7 Conclusion

The Be-walled flow cryostat has a temperature range of 10K to ambient temperature. For work below 90K liquid helium needs to be used instead of liquid nitrogen, making data collection at such low temperatures very costly. Also the time spent collecting data is limited as it is not possible to refill the supply dewar while the cryostat is operational. That is after about 3 days when using liquid helium or about a week for liquid nitrogen,

the cryostat must necessarily be allowed to warm up to room temperature. If data collection is to be continued after refilling the supply dewar, then the crystal will have to be re-centered after cooling down and reaching a stable temperature. At this stage it might not be possible to stabilize the cryostat at exactly the same temperature as before. Thus if data is to be collected in this manner then it might be neccessary to scale each set of data independently. This and the limited area of reciprocal space accessible with the cryostat makes it very difficult to collect extended accurate data sets with it. It is probably more appropriate to use this cryostat for the study of phase transitions in crystals with relatively small unit cells.

In the case of the liquid nitrogen gas-flow cryostat, data collection could in principle be continued indefinitely, as it is possible to refill the supply dewar without affecting the stability of the cryostat. This makes this cryostat extremely suitable for the collection of accurate data requiring long counting times as well as the collection of many equivalents. Such data sets would be suitable for charge density and other studies that require very accurate data.

It was possible to show that the temperature stability of both cryostats is better than 1K with the use of a Chromel-alumel thermocouple. The absolute temperatures attainable with the cryostats were also verified with this thermocouple.

Chapter Seven.

Future trends and developments.

For routine purposes only data contained within the copper sphere of reflection need generally be collected, this corresponds to a resolution of about 0.8Å. This is sufficient to resolve atomic positions and to produce the conformational data that is generally required from such studies. When a low-temperature diffraction experiment is combined with an attempt to remove all systematic errors during data capture, it becomes possible to obtain more information about the molecules in a crystal than just their xyz coordinates. To distinguish this technique from routine work Angermund, Claus, Goddard and Kruger (1985) in their review article referred to it as high resolution crystallography. In a high resolution study, typically the full Ewald sphere of reflections should be collected. The resolution attainable using this technique is of the order of 0.4 to 0.5Å.

With the aid of accurate data obtained from a high resolution x-ray diffraction experiment, it becomes feasible to look at the electron density distribution in detail. This should lead to a better understanding of chemical bonding [Coppens, 1984]. The total electron density obtained, however is rather difficult to interpret as it is dominated by the core electrons, even though this is a complete representation of the nature of the bonding in the molecule. A more useful representation is contained in the concept of an electron deformation density, [Coppens, 1989; Schwartz, Valtazanos and Ruedenberg,

1985]. In an analysis involving this concept, the spherically symmetric electron density of a free atom is subtracte ' from that found experimentally for the atom in a crystal. Thus information is at hand as to how the electron density associated with the atom changed upon bond formation or interaction in a crystal. This exercise is a very definite attempt to answer the question posed by C.A Coulson in 1971 when he said: "Clearly a molecule is much more complicated than an atom. So the question arises: what happens to an atom when it becomes part of a molecule?" [Coppens, 1977]

Another field of activity to gain from the availability of more accurate Bragg reflection data, is the interpretation of anisotropic displacement parameters (ADP's) in terms of molecular motion. What were originally termed anisotropic "vibrational parameters" or "thermal parameters" are more precisely described as anisotropic Gaussian displacement parameters. This indicates that they are not only influenced by thermal motion but are subject to disorder effects as well. The need for accurate data, stems from the recognitic that in routine structures the ADP's are frequently adversely affected by absorption, truncation or some other systematic error in the data. This has led to some authors referring to ADP's as the rubbish bin of crystallography, since most of the errors seem to collect in them even without affecting other structural parameters severely. The usefulness of ADP's were first realised by Cruickshank (1956) when he showed that such quantities for anthracene and naphthalene could be interpreted in terms of molecular rigid-body motion and hence related to spectroscopic and thermodynamic properties [Cruickshank, 1956b]. A more recent treatment by Dunitz, Schomaker and Trueblood (1988) shows how force constants, barriers to rotation and frequencies can be derived from ADP's, by treating the molecule a rigid or semi- rigid body. A more

graphical approach to this is presented by Hummel, Roselli and Burgi (1990)

Lastly the advances in high resolution crystallography is probably best exemplified by the work of Paturle, Graafsma Boviatis, Legrand, Coppens, Kvick and Wing (1989) in which they studied the influence of an external electric field on the x-ray scattering of the non-linear optical crystal 2-methyl-4-nitroaniline. The most astounding feature of this work was their ability to detect variations in integrated intensity caused by the applied field of the of the order of 0.1%.

High resolution crystallography is the logical next step to determining crystal structures at low-temperatures. This is because it requires the same experimental equipment. It only demands greater care during data capture and better data reduction methods. This greatly increases the number of applications of modern single crystal x-ray diffraction, especially within a field such as chemistry.

Chapter Eight

Concluding Discussion

During the course of this project, the main objectives set out at the start were achieved. That is the cryostats have been assembled and tested on the diffractometers also the experimental methods and techniques necessary for collecting data at low-temperatures have been developed. Initial tests relating to temperature stability and the minimum temperature reachable at the crystal position were conducted successfully. The cryostats were found to have a temperature stability of better than 1K, making them suitable for collecting accurate data. The use of the Be-walled flow cryostat in this respect is somewhat restricted due to the limited movement around the kappa axis of the diffractometer. Also its supply dewar cannot be refilled whilst the cryostat is operational.

A final evaluation of the cryostats as well as a consideration of some of the applications of low-temperature crystallography involved the determination of some crystal structures at low-temperatures. The compounds chosen for this were :N-arylpyrrolidin-2-one,4-p-hydroxyphenyl-9,10,11-trihydroxy-8-ethyl-1,7-dioxaspiro[4,4]-nona-2,6-dioneand5,6-trans,-6-Bromo-5-hydroxy-3-nitrobicyclo[2.2.2]oct-2-ene. The structure of the first was determined at three different low-temperatures.

Experience gained from these studies indicate that even with an operational cooling device, the collection of low-temperature diffraction data is not straight forward.

Unexpected events such as the crystal shattering or moving on cooling can always take place.

The consideration of hydrogen atom positions, which motivated the study of 4-p-hydroxyphenyl-9,10,11-trihydroxy-8-ethyl-1,7-dioxaspiro[4,4]-nona-2,6-dioneand5,6-trans,-6-Bromo-5-hydroxy-3-nitrobicyclo[2.2.2]oct-2-ene, as well as that of leucodrin, indicated that the technique has considerable application in this field, as the positions given to hydrogen atoms from ambient temperature data is often suspect, especially if they are associated with atoms other than carbon. In this respect, low-temperature structure determination offers significantly better and more reliable structural parameters for the hydrogen atoms, in particular and for all atoms in general.

Appendix 1

All distance measurements are quoted in Å and angles in °

Appendix 4

Programs used

1. SHELX76, Sheldrick, 1978
2. SHELXS86, Sheldrick, 1985
3. NRCVAX, Gabe, Lee and Le Page, 1985
4. SCHAKAL, Keller, 1989
5. BRISK, written during this project.
6. CENTER, written during this project.

Appendix 5

Program listings

Brisk

Structure determination and refinement was carried out using the SHELX [Sheldrick, 1985] set of programs. The program BRISK was written to facilitate the transfer of structural information, such as atomic coordinates, thermal parameters and esd's to the NRCVAX [Gabe, Lee and Le Page, 1985] system of programs. The latter was then used for geometrical calculations and for producing ORTEP [Johnson, 1965] diagrams etc. Brisk also calculates the equivalent isotropic temperature factor for anisotropically refined atoms by the method of Hamilton (1959).

$$U_{eq}=\frac{1}{3}\sum_{i=1}^{3}\sum_{j=1}^{3}U_{ij}a^*_i a^*_j(a_i a_j)$$

The error in U_{eq} is evaluated according to the method suggested by Schomaker and Marsh (1983). Finally BRISK compiles tables of fractional coordinates, anisotropic thermal parameters and selected bond lengths and angles. The latter having been calculated using the SHELX BOND instruction.
