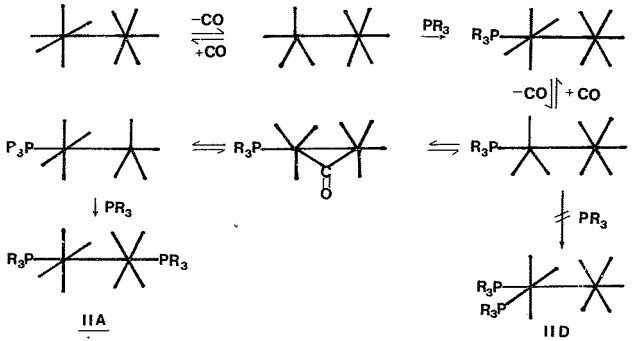

Figure 15.4: Schematic representation of the mechanism for the formation of diax-$Re_2(CO)_8(PR_3)_2$ (IIA)

105-125°]. Slow isomerization of the 1,2-ax,eq-$Re_2(CO)_8(PR_3)_2$ (R = Bu^n, Ph) complexes to diax-$Re_2(CO)_8(PR_3)_2$ was observed in toluene solution at room temperature (half-life of 10 h (PPh_3) or 1-2 days (PBu^n_3)). The 1,2-eq,eq-$Re_2(CO)_8(PR_3)_2$ complexes appear to be stable towards isomerization.

(ii) The Me_3NO-assisted reaction of $Re_2(CO)_{10}$ and PMe_2Ph in MeCN (80°C) resulted in the formation of 1,2-ax,eq-$Re_2(CO)_8(PMe_2Ph)_2$ (vide supra).

(iii) The thermal reaction between $Re_2(CO)_{10}$ and PR_3 (PR_3 = PMe_2Ph[183], $PMePh_2$[184]) at elevated temperatures and for extended reaction times (eg. PMe_2Ph, 80-100°C, 60-96 h;[183] $PMePh_2$, 140°C, 15 h[184]) yielded a product identified as 1,2-ax,eq-$Re_2(CO)_8(PR_3)_2$ (vide supra).

(iv) The photochemical reaction between $Re_2(CO)_{10}$ and PR_3 (PR_3 = PMe_2Ph,[183] $PMePh_2$[184]) has also been reported to yield the 1,2-ax,eq-$Re_2(CO)_8(PR_3)_2$. An analogous arsine derivative, 1,2-ax,eq-$Re_2(CO)_8(AsMe_2Ph)_2$, has also been prepared by the photochemical reaction of $Re_2(CO)_{10}$ with $AsMe_2Ph$.[183]

The first two cases can be explained in terms of replacement of equatorial ligand(s) from 1,2-eq,eq-$Re_2(CO)_8(L)_2$ ((i) (L)$_2$ = μ-olefin; (ii) L = NCMe), to give 1,2-eq,eq-$Re_2(CO)_8(PR_3)_2$, or 1,2-ax,eq-$Re_2(CO)_8(PR_3)_2$, depending on the size of the phosphine ligand.

In the third case, formation of 1,2-ax,eq-$Re_2(CO)_8(PR_3)_2$ products in thermal reactions of $Re_2(CO)_{10}$ with PR_3 at elevated temperatures and extended reaction times, can be explained in terms of the initial formation of diax-$Re_2(CO)_8(PR_3)_2$ (obtained from thermal reactions under less forcing conditions (shorter reaction times)[185] and from the Pd-catalysed and Me_3NO-assisted (solvent CH_2Cl_2 or $CHCl_3$[177]) reactions of $Re_2(CO)_{10}$ with PR_3), followed by metal-metal bond cleavage, and rearrangement and recombination to give the electronically favoured 1,2-ax,eq-$Re_2(CO)_8(PR_3)_2$ isomer. The formation of 1,2-ax,eq-$Re_2(CO)_8(PR_3)_2$ products photochemically (case (iv)), where Re-Re bond cleavage is likely,[266a] is consistent with this proposal. Further, traces

of 1,2-ax,eq-$Re_2(CO)_8(PR_3)_2$ *isomer can* be detected by IR spectroscopy in the cases of the reactions which give the diax-$Re_2(CO)_8(PR_3)_2$ *isomer* (*vide supra*), suggesting that a small amount of isomerization to the 1,2-ax,eq-$Re_2(CO)_8(PR_3)_2$ *isomer occurs even under milder reaction conditions.* As described above, partial isomerization of diax-$Re_2(CO)_8(PMe_2Ph)_2$ to 1,2-ax,eq-$Re_2(CO)_8(PMe_2Ph)_2$ in toluene solution (80°C, 4 h) has also been observed (under normal laboratory light). Thus a slow thermal isomerization of diax-$Re_2(CO)_8(PR_3)_2$ to 1,2-ax,eq-$Re_2(CO)_8(PR_3)_2$ can occur, provided the phosphine is not too large (*vide infra*).

Steric factors determine whether the 1,2-ax,eq-$Re_2(CO)_8(PR_3)_2$ isomer is stable for a particular phosphine. Thus for PMe_2Ph and $PMePh_2$ (Tolman cone angles[83] of 122° and 136° respectively), the 1,2-ax,eq-$Re_2(CO)_8(PR_3)_2$ isomers are obtained from the thermal reaction of $Re_2(CO)_{10}$ with PR_3 (case (ii)), but the thermal reaction between $Re_2(CO)_{10}$ and PPh_3 (Tolman cone angle[83]: 145°) yields only diax-$Re_2(CO)_8(PPh_3)_2$ (140°C, 16 h).[182] Further, no 1,2-ax,eq-$Re_2(CO)_8(PPh_3)_2$ (as evidenced by sidebands in the IR spectrum of the diax-$Re_2(CO)_8(PPh_3)_2$ product) is formed in the Pd0-catalysed reaction of $Re_2(CO)_{10}$ and PPh_3 (*vide supra*).

Thus it would appear that the particular synthetic method employed, and the size of the phosphine ligand used, determine whether the diax-, 1,2-eq,eq- or 1,2-ax,eq-$Re_2(CO)_8(PR_3)_2$ isomer will be obtained. For a synthetic method predisposed towards the formation of equatorially substituted $Re_2(CO)_8(PR_3)_2$ isomers (cases *(i)-(iv) above*), 1,2-eq,eq-$Re_2(CO)_8(PR_3)_2$ is obtained for small phosphines (Tolman cone angle *range:* 105°-121°), *while large phosphines* (Tolman cone angle range: 122°-145°) yield 1,2-ax,eq-$Re_2(CO)_8(PR_3)_2$. *For the larger phosphine* ligands (Tolman cone angle range: 130°-145°), the 1,2-ax,eq-$Re_2(CO)_8(PR_3)_2$ isomers are *unstable, and* slowly isomerize (rate increases with the size of the PR_3 ligand) to diax-$Re_2(CO)_8(PR_3)_2$.

15D.2 Experimental

15D.2.1 Synthesis of $Re_2(CO)_{10-n}(PR_3)_n$ ($n = 1,2$) from the reaction of $Re_2(CO)_{10}$ and PR_3 in the presence of Pd-catalysts

$Re_2(CO)_{10}$ (163 mg, 0.25 mmol) and 50 mg Pd-catalyst (Pd/C (10% Pd), $Pd/CaCO_3$ (10% Pd) or PdO) were stirred in xylene (10 mℓ), to which was added PR_3 (0.75 mmol). The reaction solution was refluxed at 140°C for 1 to 9 h, depending on the phosphine used (see Table 15.5). The progress of the reaction was monitored by TLC (Silica; eluent: ethylacetate: petroleum ether (80-100°C), 1:3). The product(s) were isolated by preparative layer chromatography (Silica; eluent as for TLC), extracted with benzene, and crystallized from benzene-hexane solution, to yield colourless to yellow solids.

15D.2.2 Synthesis of $Re_2(CO)_{10-n}(PR_3)_n$ ($n = 1,2$) by the NMe_3O-assisted reaction of $Re_2(CO)_{10}$ with PR_3 and $CH_2Cℓ_2$

$Re_2(CO)_{10}$ (163 mg, 0.25 mmol) was dissolved in $CH_2Cℓ_2$ (10 mℓ), to which PR_3 (0.75 mmol) was added, followed by $NMe_3O \cdot 2H_2O$ (60 mg, 0.54 mmol) dissolved in degassed MeOH (5 mℓ). The reaction solution was heated at 40°C for 8 h. The progress of the reaction was monitored by TLC (Silica; eluent: ethylacetate: petroleum ether (80-100°C), 1:3). The products were isolated by preparative layer chromatography (Silica; eluent as for TLC), extracted with $CH_2Cℓ_2$, and recrystallized from $CH_2Cℓ_2$-pentane solution, to yield colourless to yellow solids.

15D.2.3 Preparation of an isomer of $Re_2(CO)_8(PMe_2Ph)_2$

$Re_2(CO)_{10}$ (653 mg, 1 mmol), was dissolved in acetonitrile, MeCN (10 mℓ), and the solution heated at 80°C. To this solution was added $NMe_3O \cdot 2H_2O$ (234 mg, 2.1 mmol) dissolved in degassed MeOH (10 mℓ). Reaction was instantaneous, as evidenced by the colour change of the reaction solution from colourless to pale yellow. Then PMe_2Ph (2.1 mmol) was added to the reaction solution, and the mixture heated at 80°C for 2 h. The product was isolated by column chromatography (2cm x 40cm column, silica; gradient elution with hexane-

benzene solutions, starting with hexane and ending with benzene). Recrystallization from CH_2Cl_2-pentane solution gave a cream solid.

15D.2.4 Preparation of an isomer of $Re_2(CO)_8(PMePh_2)_2$

$Re_2(CO)_{10}$ (667 mg, 1.02 mmol) and $PMePh_2$ (4.0 mmol) were refluxed in xylene (17 mℓ) at 138°C for 15 h. During this time the solution changed from colourless to an intense yellow. The xylene was removed on a rotary evaporator, and the yellow oily residue pumped under vacuum for several days to remove excess phosphine, to give a yellow solid.

15E. The Crystal and Molecular Structure of diax[$Re_2(CO)_8(PMe_2Ph)_2$]

15E.1 Introduction

Although the crystal and molecular structures of three $Mn_2(CO)_{10-n}(PR_3)_n$ ($n = 1$,[224] 2[255-6]) compounds have been determined by X-ray crystallography, no analogous dirhenium carbonyl-phosphine complexes have been studied crystallographically.

From IR spectral data (see section 15B), the geometry of the majority of $Re_2(CO)_9(PR_3)$ and $Re_2(CO)_8(PR_3)_2$ products is expected to be the same as that of the analogous $Mn_2(CO)_9(PR_3)$ and $Mn_2(CO)_8(PR_3)_2$ complexes, viz. axial and diaxial phosphine substitution respectively. An X-ray crystallographic study of the complex diax[$Re_2(CO)_8(PMe_2Ph)_2$], product of the PdO-catalysed reaction between $Re_2(CO)_{10}$ and PMe_2Ph (see section 15D), was undertaken with a view to confirming this prediction.

Further, the structural investigation of diax[$Re_2(CO)_8(PMe_2Ph)_2$] was undertaken as part of an extension of the chemical, mechanistic and structural studies of isonitrile derivatives of dirhenium decacarbonyl (see chs. XI and XIV) to other donor ligands. Specifically, the structural effect (if any) of the bulkier phosphine ligand (Tolman cone angle[81] for PMe_2Ph: 122°; values from MO calculations[254]: 139.8° (staggered), 155.6° (eclipsed)) on the $Re_2(CO)_8$ unit was of interest. For example, increased

steric bulk could affect the phenomenon of the bending in of the equatorial carbonyl ligands towards the metal-metal bond, observed in the parent carbonyl, $Re_2(CO)_{10}$,[118] and in a series of dirhenium decacarbonyl-isonitrile derivatives, $Re_2(CO)_{10-n}(CNR)_n$ (n = 1-4) (see ch. XIV).

15E.2 Discussion of related $Mn_2(CO)_{10-n}(PR_3)_n$ (n = 1,2) Structures

As has been mentioned, no crystallographic studies of $Re_2(CO)_{10-n}(PR_3)_n$ (n = 1-4) complexes have been reported. However, X-ray crystallography has been used to determine the structures of the related manganese complexes, ax-$Mn_2(CO)_9(PMe_2Ph)$,[224] diax-$Mn_2(CO)_8(PMePh_2)_2$[255] and diax-$Mn_2(CO)_8(PEt_3)_2$.[256] Although bond length values for the manganese complexes cannot be compared to those of $[Re_2(CO)_8(PMe_2Ph)_2]$, overall molecular conformation is comparable. The salient structural features of the $Mn_2(CO)_{10-n}(PR_3)_n$ (n = 1,2) complexes will thus be discussed.

Crystal data and selected bond parameters for the $Mn_2(CO)_{10-n}(PR_3)_n$ (n = 1,2) structures are given in Table 15.8. In all three cases, the dimer adopts a staggered conformation, with C-Mn-Mn-C torsion angles close to the ideal 45°. For the mono-substituted $Mn_2(CO)_9(PMe_2Ph)$, the phosphine ligand occupies an axial position; for the bisphosphine complexes, $Mn_2(CO)_8(PR_3)_2$ (PR_3 = $PMePh_2$, PEt_3), phosphine substitution is diaxial. The observation that phosphine ligands occupy axial sites, rather than electronically favoured equatorial positions, is rationlized in terms of the steric requirements [Tolman cone angles[65]: PMe_2Ph, 122°; PEt_3, 132°; $PMePh_2$, 136°] of the bulky phosphine ligands[112] (see Section 15D; see also ch. XII for a discussion of electronic and steric factors governing ligand site preference in $M_2(CO)_{10}$ (M = Re,Mn) complexes).

Interestingly, an X-ray crystallographic structure determination of $Mn_2(CO)_8(AsMe_2Ph)_2$[255] has shown that this molecule has an eclipsed conformation, with an arsine ligand occupying an equatorial site on each Mn-atom. This crucial difference is ascribed to the longer Mn-As bond distance (av. 2.46Å, cf. av. Mn-P, 2.23Å, for diax-$Mn_2(CO)_8$-

$(PMePh_2)_2$[235]) which reduces repulsion between substituent groups and the carbonyls, hence permitting the electronically favoured equatorial substitution. Steric strain in this molecule is however reflected in the marked angular distortions (eg. Mn-Mn-As: 103°, instead of the ideal 90°) caused by close contacts between the phenyl ring and two of the equatorial carbonyls on the other Mn-atom. The unusual eclipsed conformation is probably adopted in order to minimize repulsions between the arsine substituents and the equatorial CO ligands, as repulsive interactions between the two sets of carbonyl groups is expected to be greater in the eclipsed than in the staggered conformation.[126]

Significantly, for all the three $Mn_2(CO)_{10-n}(PR_3)_n$ (n = 1,2) structures, the Mn'-Mn-COeq bond angles are less than 90°, ie. the equatorial carbonyls bend in towards the Mn-Mn bond. The significance of this will be discussed in section 15E.3.4.

In all three structures, the Mn-C-O bond angles are in the range 171 - 178°, as expected.[19]

15E.3 Discussion of the structure of diax[$Re_2(CO)_8(PPhMe_2)_2$](VII)

The molecular structre of diax[$Re_2(CO)_8(PPhMe_2)_2$](VII), and the numbering system used in the crystal structure determination, is shown in Fig. 15.5. The compound crystallizes in the monoclinic centrosymmetric space group C2/c, with Z = 4. A view of the unit cell, looking down the b-axis, is shown in Fig. 15.6. Bond lengths and bond angles are given in Tables 15.9 and 15.10 respectively. Average bond angle and bond length data is summarized in Table 15.11. The molecule adopts a staggered conformation, with diaxial phosphine substitution. The main structural features will be discussed in detail.

15E.3.1 Diaxial phosphine substitution

The two phosphine ligands occupy the axial positions, as expected from IR data (section 15D). This is in contrast to the structure of $Re_2(CO)_8(CNC_6H_3Me_2\text{-}2,6)_2$ (see ch. XIV), where the two isonitrile ligands occupy electronically favoured equatorial sites. This is an example of the

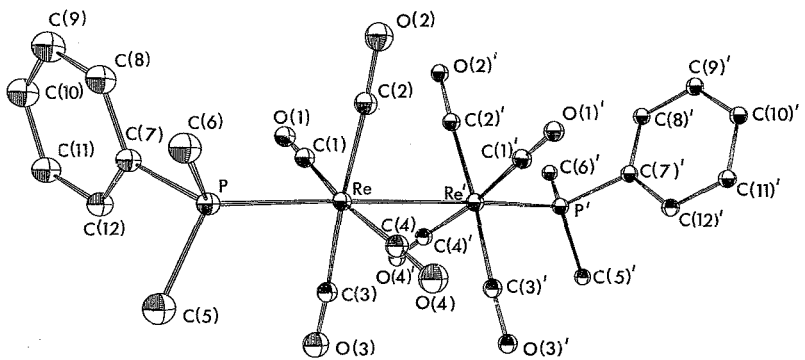

Figure 15.6: ORTEP[45] view of the diax $[Re_2(CO)_8(PMe_2Ph)_2]$ molecule (VII), showing the numbering system used. (Re related to Re' by a 2-fold axis, generating the equivalent position $(-x, y, \frac{1}{2}-z)$, and similarly for the other atoms).

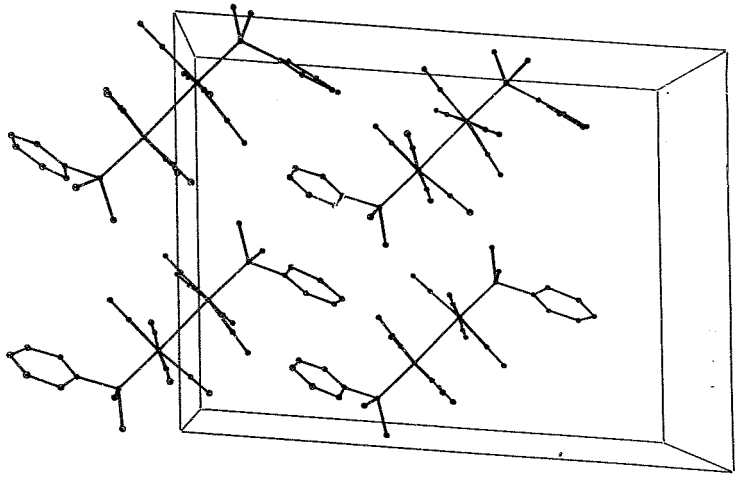

Figure 15.6: ORTEP[45] view of the unit cell of diax-$[Re_2(CO)_8(PMe_2Ph)_2]$ (..I), looking down the b-axis.

dominance of steric factors over electronic site preference in the case of the bulky phosphine ligand. (For the $Re_2(CO)_8(CNC_6H_3Me_2\text{-}2,6)_2$ and $Re_2(CO)_8(PPhMe_2)_2$ structures, the bulky $C_6H_3Me_2$-2,6 groups are much further removed from the Re atom than the $PPhMe_2$ groups viz. adding the av. bond lengths for the linear Re-CN (2.05Å), C-N (1.15Å) and N-C(R) (1.43Å) bonds gives an effective av. Re...C(R) distance of 4.63Å, cf. Re-P distance of 2.35Å; the lesser steric bulk of the isonitrile ligand is also reflected in the "fan-shaped" angles[44] for $CNC_6H_3Me_2$-2,6 of 106° (wideness) and 53° (thickness)).

Axial substitution has also been observed in related $Mn_2(CO)$ (n = 1,2) structures (see section 15E.2). The di- derivative, $Mn_2(CO)_8(CNBu^t)_2$ ("fan-shaped" angles[44] for $CNBu^t$: 70° (wideness) and 68° (thickness)) is again equatorially substituted (see ch.XIV). Hence the size of the metal atom seemingly has no effect on the substitution geometry.

15E.3.2 The Re-Re, Re-P and Re-CO bond lengths

In diax$[Re_2(CO)_8(PMe_2Ph)_2]$ the Re-Re bond length is 3.044(1)Å, only fractionally longer than that of 3.041(1)Å in the parent carbonyl, $Re_2(CO)_{10}$.[158] The substitution of a carbonyl trans to the metal-metal bond by a poorer π-accepting[43a] phosphine ligand, and the consequent increase in electron density on the metal atoms, perhaps in anti-bonding orbitals,[274] might be expected to result in an increase in metal-metal bond length. Such effects have been observed for phosphine-substituted metal clusters eg. $Fe_3(CO)_{11}(PPh_3)$,[275] $Ru_3(CO)_{11}(PPh_3)$,[276] $Os_3(CO)_{11}$-$[P(OMe)_3]$,[277] $(Os_3(CO)_{17}[P(OMe)_3]_4)$,[278] and has also been ascribed to ligand packing effects, ie. congestion between phosphine and carbonyl groups causes expansion of the metal core.[279-281] Further, kinetic studies[282] have shown that the Mn-Mn bond strength in $Mn_2(CO)_8(PR_3)_2$ is less than in $Mn_2(CO)_{10}$.

The av. Re-CO bond length is 1.94(2)Å, similar to that of 1.976(6)Å for the av. Re-CO(trans to CO) bond length

15E.3.3 Molecular conformation

Although the two sets of eq-carbonyl groups are staggered with respect to each other, the C-Re-Re-C torsional angles (see Appendix C,(VII)) deviate an av. of 6.9° from the ideal 45° (see Fig. 15.7). This is probably due to the influence of crystal packing forces (see section 15E.3.6).

The conformation of the ax-(PMe_2Ph) groups with respect to the eq-CO groups is interesting in that the phenyl rings of the axial phosphine groups each eclipses a carbonyl ligand (see Fig. 15.8), with torsional angle (see Appendix C,(VII)) of 0.0 for C(1)-Re-P-C(7). This feature could be due to :-

(i) steric factors: the methyl groups are then in staggered positions with respect to the eq CO's (see Fig. 15.8(b)), with the smallest OC-Re-P-CH_3 torsional angle being 27.7°. However, in diax-$Mn_2(CO)_8(PEt_3)_2$,[236] all three ethyl groups are staggered with respect to the eq CO ligands.

(ii) electronic factors: possible interactions between the π-cloud of a phenyl ring and an eclipsed CO.

(iii) crystal packing forces (see section 15E.3.6).

The phenyl rings align parallel to the plane of the eq carbonyl groups, as necessitated by steric factors. The two phenyl rings deviate from co-planarity by 30.8° The phenyl rings are slightly puckered (see Table 15.12).

The av. Re-P-C and C-P-C bond angles of 115.5(8)° and 102.8(11)° respectively, and the av. P-C bond length of 1.83(2)Å, are similar to those for the related $Mn_2(CO)_{10-n}(PR_3)_n$ (n = 1,2) structures (see Table 15.8).

15E.3.4. P-Re-CO, OC-Re-CO and Re-Re-CO bond angles

The axP-Re-COeq bond angles are obtuse (av. 92.9(6)° the eqOC-Re-COeq bond angles close to 90° (av. 89.9(8)°, and the Re-Re-COeq bond angles acute (av. 87.2(5)°, ie. the equatorial carbonyls bend in towards the Re-Re bond. This

effect of the bending in of the equatorial CO ligands towards the metal-metal bond is observed for related $Mn_2(CO)_{10-n}(PR_3)_n$ (n = 1,2) complexes (section 15E.2), as well as for a series of $M_2(CO)_{10-n}(CNR)_n$ (M = Re, n = 1-4; M = Mn, n = 2,4) complexes (ch. XIV) and the parent carbonyls, $M_2(CO)_{10}$ (M = Re,Mn).[138] Hence this phenomenon would appear to be an electronic effect, unaffected by steric considerations. Various explanations have been proposed (see ch. XII), and Elian and Hoffmann[98] have predicted the effect on the basis of MO calculations.

15E.3.5 Re-C-O bond angles

The Re-C-O bond angles are in the range 177(2)° to 178(2)° (av. 177.5°). Slight deviations from linearity (ca. 5°) of M-C-O ligands is expected.[39]

15E.3.6 Packing

The overall conformation adopted by the molecule could be governed largely by crystal packing forces. The molecules pack in a regular fashion (Fig. 15.6). A notable feature is the way in which the phenyl rings of different molecules line up in rows down the cell.

According to Johnson's[248] model of close-packing of CO's for metal carbonyl complexes, packing forces are responsible for distortions from ideal geometry. Crystal packing forces could account for several observed distortions in the diax-$[Re_2(CO)_8(PMe_2Ph)_2]$ molecule:-

(i) An av. 6.0° deviation from ideal 45° C-Re-Re-C torsional angle.

(ii) The slight deviation of the P-Re-Re-P unit from linearity, as evidenced by the P-Re-Re bond angle of 177.2(5)°

(iii) The deviation of the phenyl rings from co-planarity. (Angle between mean planes of the two phenyl rings: 30.8°).

(iv) The deviation from parallel alignment of the phenyl rings with the planes of the C-atoms of the eq carbonyl groups. (Angles between mean planes: Ph(C(7) to C(12)) and eq C-atoms (C(1) to C((4)): 21.3°; Ph(C(7)′ to C(12))′ and eq C-atoms (C(1)′ to C(4)′: 21.3°).

Other structural features that could be largely determined by crystal packing forces are the orientation of the PMe_2Ph groups with respect to the eq CO's such that the phenyl rings eclipse an eq carbonyl, and the position of the phenyl groups relative to each other (ie. which CO ligand is eclipsed by the Ph rings). The role of crystal packing forces in determining overall molecular conformation should not be neglected.

15E.4 Experimental

15E.4.1 Data collection

The compound diex$[Re_2(CO)_8(PMe_2Ph)_2]$ was synthesized in the PdO-catalysed reaction between $Re_2(CO)_{10}$ and PMe_2Ph (section 15D). Recrystallization from diethylether-pentane solution under nitrogen at 20°C yielded fine colourless needlelike crystals.

Preliminary investigation by standard Weissenberg photography established the space group as the centred monoclinic C2/c, or the non-centrosymmetric Cc, from the absences $hk\ell$, $h + k = 2n$, $h0\ell$, $\ell = 2n$ ($h = 2n$) and $0k0$, $k = 2n$. Refined cell constants were obtained during data collection on a Philips PW1100 four-circle diffractometer, using graphite-monochromated MoKα radiation ($\lambda = 0.7107$Å) at room temperature (20°C). Lorentz and polarization corrections were applied, and the data were empirically corrected for absorption effects using the program DIFABS, written by N. Walker and D. Stuart,[117a] and adapted by G. Kruger.[117b] Crystal data and details of the structure analysis are summarized in Table 15.13.

15E.4.2 Structure solution and refinement

Structure analysis and refinement were carried out using the program SHELX82.[116a] Initial co-ordinates for the rhenium atoms were derived from a Patterson synthesis, and the positions of the other non-hydrogen atoms were found by difference Fourier syntheses. The structure was refined in the centrosymmetric space group C2/c (No. 15).* The two halves of the molecule being related by a crystallographic 2-fold axis. Positional parameters for all atoms,

and anisotropic temperature factors for the rhenium and phosphorous atoms, were refined by full-matrix least-squares analyses. In the initial stages, the phenyl rings were treated as rigid hexagons, but all restraints were removed in the later stages of refinement. Least-squares refinement was considered completed when all parameter shifts were less than 0.5σ. At this stage the R-value was 0.0602, Unit Weights were used. Scattering factors for Re(0) were taken from "International Tables for X-ray Crystallography",[46b] and anomalous dispersion corrections[46c] for rhenium were made.

Final atomic co-ordinates for all atoms, and isotropic temperature factors of the carbon and oxygen atoms are given in Table 15.14, and Table 15.15 gives the anisotropic temperature factors of the rhenium and phosphorous atoms. A listing of the Structure Factors is to be found in Appendix D.

---

* The structure was also refined in the non-centrosymmetric space group, Cc (No. 9), and Hamilton's Statistical Significance Test on the Crystallographic R Factor[285] applied. At the 0.005 significance level, it was found that the hypothesis that the space group is C2/c and not Cc, could not be rejected.

XVI. Conclusion

The synthetic utility of catalysts such as PdO (alone or in combination with $[(\eta^5C_5Me_5)Fe(CO)_2]_2$) to bring about the substitution of CO by RNC ligands in transition metal carbonyl complexes under mild thermal conditions has been demonstrated for a wide variety of metal carbonyl complexes, including $(Arene)Cr(CO)_3$, $(C_5H_5)Mn(CO)_3$ and $Re_2(CO)_{10}$. This catalytic synthetic route provided access to novel isonitrile-substituted derivatives of these carbonyl complexes, thus making the derivatives available for further chemical and structural studies.

X-ray crystallographic studies of representative isonitrile-substituted metal carbonyl derivatives were undertaken to establish the stereochemistry of the products. From an analysis of the bond data from these studies, together with a comparison of the structure to that of the unsubstituted parent carbonyl complex, the structural effect of ligand substitution was evaluated. Trends were rationalized in terms of electronic effects, and deviations explained by the influence of steric factors and/or crystal packing forces. Further, with the backing of the crystallographic studies, the relationship between molecular structure and IR spectral data was examined.

The crystal and molecular structures of $(\eta^5C_5H_5CO_2Me)$-$Cr(CO)_2(CNBu^t)$ and $(\eta^5C_5H_5)Mn(CO)_2(CNBu^t)$ were undertaken largely in order to establish whether the anomalous IR spectra of these complexes could be explained in terms of molecular structure. No definite conclusion could be reached in this regard, but possible explanations for the anomalous IR data were advanced. If the effect is due to the bent C-N-C bond, crystal structure determinations of similar complexes which do not show the anomalous IR spectral behaviour, eg. $Cr(CNC_6H_3Me_2\text{-}2,6)$ (attempts to solve this structure unsuccessful), $(\eta^5C_5H_5)Mn(CO)_2(CNC_6H_3Me_2\text{-}2,$ may help clarify the issue, as such complexes would thus be expected to have a linear C-N-C bond. No explanation of the anomalous IR spectra of

the $Fe(CO)_3(CNR)_2$ complexes could be found from the crystal and molecular structure of $Fe(CO)_3(CNMe)_2$. The reason for the anomalous IR data is unclear.

A systematic study (spectral, structural and mechanistic) was conducted of the $Re_2(CO)_{10-n}(CNR)_n$ (n = 1-4) complexes. From an X-ray crystallographic study of a series of representative derivatives, viz. $Re_2(CO)_9(CNBu^t)$, $Re_2(CO)_8(CNC_6H_3Me_2\text{-}2,6)_2$, $Re_2(CO)_7(CNMe)_3$ and $Re_2(CO)_6(CNC_6H_3Me_2\text{-}2,6)_4$, it was shown that the increasing degree of isonitrile substitution has little structural effect on the dimer, relative to the parent carbonyl, $Re_2(CO)_{10}$. In particular, the equatorial ligands (both CO and CNR) bend in towards the rhenium-rhenium bond, as in $Re_2(CO)_{10}$, despite the increased steric bulk of the isonitrile ligands. Further, the poorer π-accepting RNC ligands do not result in an increase in the Re-Re bond length for the $Re_2(CO)_{10-n}(CNR)_n$ (n = 1-3) complexes, although a slight lengthening is observed for $Re_2(CO)_6(CNC_6H_3Me_2\text{-}2,6)_4$. A shortening of the Re-CO bonds trans to an RNC is however a general trend. The structures of two manganese analogues, $Mn_2(CO)_8(CNBu^t)_2$ and $Mn_2(CO)_6(CNC_6H_3Me_2\text{-}2,6)_4$, were also determined crystallographically. The above features are applicable, but here a lengthening of the Mn-Mn bond relative to that in $Mn_2(CO)_{10}$ is observed.

It was found that the differences in the IR and ^1H NMR spectra of the $Re_2(CO)_8(CNR)_2$ and $Mn_2(CO)_8(CNR)_2$ derivatives could be explained in terms of differences in the substitution geometry, as demonstrated by the crystal structure determinations of 1,2-dieq-$Re_2(CO)_8(CNC_6H_3Me_2\text{-}2,6)_2$ and 1,1-cis-dieq-$Mn_2(CO)_8(CNBu^t)_2$. Kinetic studies on $M_2(CO)_{10-n}(CNBu^t)_n$ (M = Mn, Re; n = 1-3) are in progress[23] and should provide information on the formation of isomers and the reaction pathways.

An X-ray crystal structure determination confirmed the diax-substitution of $Re_2(CO)_8(PMe_2Ph)_2$, obtained from the PdO-catalysed reaction of $Re_2(CO)_{10}$ and PMe_2Ph. However, an ax-eq isomer was prepared by alternate methods.

The substitution geometry of the latter isomer was established by IR spectral methods.

From a consideration of IR spectral data of $M_2(CO)_8(L)_2$ (M = Re,Mn) complexes, backed up by X-ray crystallographic structural information, it was found to be possible to establish a correlation between IR spectral data (number of ν(CO) bands, and intensity pattern) and molecular geometry. This has been done for all known isomers of $M_2(CO)_8(L)_2$, viz. 1,2-diax, 1,2-ax,eq, 1,2-eq,eq, 1,1-ax,eq and 1,1-cis-dieq. A synthetic challenge would be to tailor-make the missing isomer, 1,1-trans-dieq-$M_2(CO)_8(L)_2$, to complete the set.

This work demonstrated that the catalytic synthetic route opens up new areas of metal carbonyl-isonitrile chemistry. Extensions of this method to other complexes can be invisaged, for exa[illegible]he full potential of the reaction between $(\eta^5C_5H_5)V$[illegible]RNC in the presence of Pd-catalyst, is being further explored.[279]

The approach of investigating substitution geometry and and structural effects of increasing ligand substitution, exemplified by the $Re_2(CO)_{10-n}(CNR)_n$ (n = 1-4) study, could be extended to other systems. Specifically, the $Re_2(CO)_{10-n}$[illegible]$_n$ system could be further investigated. With str[illegible]ural data from X-ray studies of isomers of $Re_2(CO)_7(PR_3)_3$, together with IR spectra, a correlation could be established between IR data and substitution geometry, as has been demonstrated for the $M_2(CO)_8(L')_2$ case.

In this work, monomeric and dimeric metal carbonyl complexes were studied. A logical extension would be to trimeric complexes. Trimers can be of two types, viz. triangular (closed) eg. $Os_3(CO)_{12}$[illegible] or oper, linear eg. $[Mn_3(CO)_{14}]^-$,[277] or bent eg. [illegible]$Mn(CO)_{14}]$.[281] Few systematic investigations have been reported on this latter class of compounds. Structural studies on these higher clusters along the lines of the $Re_2(CO)_{10}$/RNC structural study would be expected to provide valuable information regarding the substitution geometry, molecular conformation and structural trends.

Appendix A

The Sources of Chemicals used in this study

All materials were used as obtained from the manufacturers, without further purification

(A) General Chemicals

(a) Strem Chemicals Incorporated: $Re_2(CO)_{10}$, $[(C_5H_5)Fe(CO)_2]_2$, $(C_6H_6)Cr(CO)_3$, $(C_6H_5Me)Cr(CO)_3$, $(C_5H_5)Mn(CO)_3$, $(C_5H_5)V(CO)_4$, $Cr(CO)_6$, $Fe(CO)_5$, PMe_2Ph, $PMePh_2$, PMe_3, $P(CH_2C_6H_5)$, $AsMe_2Ph$.

(b) Fluka AG: ^tBuNC, 2,6-$Me_2C_6H_4NC$, $C_6H_{11}NC$, $NMe_3O.2H_2O$.

(c) Merck Chemicals: PPh_3, $LiAlH_4$.

(d) British Drug Houses Ltd.: $P(OMe)_3$, $CaCO_3$, $C_6H_5CO_2Me$.

(e) Aldrich Chemical Co. Ltd.: $C_6H_5CH_2NC$.

(f) Schuch: $CClCO_2Me$

(B) Catalysts Supported metals, metals and metal oxides.

(a) Strem Chemicals Incorporated: Re/C(5% Re), Pd/$BaCO_3$(5% Pd), Pd/$BaSO_4$(5% Pd), Pd/Al_2O_3(5% Pd), Pt/Al_2O_3(5%Pt).

(b) Engelhard: Pd/C(5% Pd), Pt/C(5% Pt), Rh/C(5% Rh), Ru/C(5% Ru).

(c) Merck Chemicals: Pd/$CaCO_3$(10% Pd), Pd/C(10% Pd), Pt/C(10% Pt).

(d) Johnson Matthey Chemicals Ltd.: PdO, PtO_2, Pd(metal).

(e) Analar: Zn(metal).

(f) Pierce Chemical Co. Ltd.: Pd-impregnated polymer (40 mesh).

(g) In addition, Activated Carbon, "Bergswerksverband", GmbH Type PK221, was a gift from Dr. G.J. McDougal.

(C) Other Sources

(a) The following compounds were gifts from Dr. M.O. Albers: $[(C_5Me_5)Fe(CO)_2]_2$,[21] $[(C_5H_5)Fe(CNC_6H_3Me_2\text{-}2,6)_2]_2$,[23] $(C_6H_5Cl)Cr(CO)_3$,[11a] $CoCl_2.2H_2O$,[142] MeNC,[262] and the $Fe(CO)_3(CNMe)_2$[142] used in the X-ray structure analysis.

Appendix A (contd)

(b) The *following* compounds were gifts from Dr. N.J. Coville: The samples of $Mn_2(CO)_8(CNBu^t)_2$ and $Mn_2(CO)_8(CNC_6H_3Me_2\text{-}2,6)_2$[220] used in the X-ray structure analyses, and the isotopically labelled $Re_2(^{13}CO)_{10}$.[221]

(c) The sample of ax-$Mn_2(CO)_9(PMe_2Ph)$ used for recording the IR spectrum (Fig. 11.2(b)) was a gift from Dr. E. Singleton.[133]

Appendix B

General Experimental Details

(a) Synthetic Methods

All reactions were routinely carried out under an inert atmosphere of argon in an appropriate round-bottomed flask. Oil baths (pre-set to the appropriate temperature) were used for the heating of the reaction solution. Generally, all solvents were deoxygenated prior to use by a rapid stream of nitrogen passed through the solvent.

Column chromatography was carried out using silica gel (Merck, "Kieselgel 60", 60-200μm). Thin layer chromatography (TLC) was carried out on silica gel (Merck, silica gel 60 F-254), and preparative layer chromatography was performed using silica gel plates (Merck, silica gel 60 F-254, 20 x 20cm, layer thickness 2 mm).

Operations such as filtration, chromatography and routine recrystallizations, were generally carried out in air, unless otherwise stated.

For the purposes of obtaining crystals suitable for X-ray analysis, slow recrystallizations were carried out either under nitrogen in a suitable solvent system at room temperature, of in a deoxygenated solution at -5°C.

(b) Solvents

The following solvents were distilled under an atmosphere of nitrogen, prior to use:

(i) benzene and tetrahydrofuran (THF), from sodium benzophenone ketyl

(ii) toluene and xylene, from sodium

(iii) hexane, heptane and dichloromethane, from calcium hydride

(iv) pentane, from sodium benzophenone ketyl, with diglyme (diethylene glycol dimethyl ether).

(c) Instrumentation

Infra red spectra were recorded using either a Pye Unicam SP300 or a Jasco IRA 1 instrument. The IR spectra of the $Re_2(CO)_{10-n}(CNR)_n$ (n = 1-4) derivatives were recorded on a Pye Unicam SP300

Appendix B (contd)

spectrophotometer, at X5 expansion.

FTIR spectra were run on a Bruker IFS 85 FTIR spectrophotometer.

All ^{1}H NMR spectra were recorded using a Bruker WP80 FTNMR spectrometer. Spectra were run in C_6D_6, relative to TMS (tetramethylsilane).

ss spectra were all obtained using a Varian MAT CH5 spectrometer (operating at 70eV).

Melting points were determined using a Kofler micro-hotstage apparatus, and are all uncorrected.

Microanalyses were all performed by the Microanalytical Division of the National Chemical Research Laboratories, South African Council for Scientific and Industrial Research (Pretoria).

(d) X-ray data collection

Preliminary investigations were by standard Weissenberg and precession methods. For the photographic work a Seifert X-ray generator, using Ni-filtered monochromatic CuKα radiation(λ = 1.5418Å), was employed. The Space Group was determined from the systematic absences, and cell constants were measured from the photographs.

Refined cell constants were obtained during data collection on a Philips PW1100 four-circle diffractometer with MoKα (λ= 0.7107Å) or CuKα (λ= 1.5418Å) graphite-monochromated radiation, using $\omega/2\theta$ scans. The cell constants were obtained by least-squares refinement of the θ values of 25 general reflections in the measured θ range. During data collection, the intensity of certain standard reflections were checked at intervals, to ensure that crystal deterioration was not observed. The data collection was performed at the National Physical Research Laboratories, South African Council for Scientific and Industrial Research (Pretoria).

(e) Crystallographic Computing Programs

SHELX82: Program for Crystal Structure Determination, by G. Sheldrick - used for structure solution and refinement.

XANADU : Program for crystallographic calculations by P. Roberts and G. Sheldrick - used to calculate torsional angles and the best least-squares plane through atoms, with deviations of atoms from the mean plane.

Appendix B (contd)

DIFABS : Program for correcting diffractometer data for absorption effects, by N. Walker and D. Stuart,[217a] adapted by G.J. Kruger[217b] - used to correct data for absorption in the case of the Re_2 structures.

ORTEP : A Fortran Thermal-Ellipsoid Plot Program for Crystal Structure Illustrations by C.K. Johnson[45] - used to plot diagrams of the molecules and unit cells for the crystal structures.

(f) Crystallographic R-indices

(i) The internal consistency R-index: R is defined as $R = [\Sigma(N.\Sigma(w(F(mean)-F)^2))/\Sigma((N-1).\Sigma(wF^2))]^{\frac{1}{2}}$ where the inner summations are over the N equivalent reflections averaged to give F(mean), and the outer summations are over all unique reflections.

(ii) The conventional R, $R = \Sigma||Fo|-|Fc||/\Sigma|Fo|$, where Fo is the observed structure factor, and Fc the calculated structure factor.

(iii) The weighted R, Rw, $Rw = \Sigma|Fo-Fc|w^{\frac{1}{2}}/\Sigma|Fo|w^{\frac{1}{2}}$, where w is the weighted used ($w = k/(\sigma^2 F)$, k being redetermined after each structure factor calculation).

Appendix C

Torsional Angles for the $M_2(CO)_{10-n}(L)_n$ Structures (M = Re, L = RNC, n = 1-4; M = Mn, L = RNC, n= 2,4; M = Re, L = PMe_2Ph, n = 2)

The program XANADU, written by Paul Roberts and G. Sheldrick, was used to calculate torsional angles for the $M_2(CO)_{10-n}(L)_n$ structures, using the SHELX[348a] output of the final atomic co-ordinates from the crystal structure determinations to perform the calculations.

The torsional angle C(n)-Re(1)-Re(2)-C(m) is defined as the angle between the vector Re(1)-C(n) and the vector Re(2)-C(m), when viewed down Re(1)-Re(2). The sign of the torsional angle is positive if Re(1)-C(n) is to be rotated clockwise into Re(2)-C(m), and negative if anticlockwise.

In the case of the structure diax[$Re_2(CO)_8(PMe_2Ph)_2$](VII), the C(x)-Re-P-C(y) torsional angles are [illegible]ly defined.

Torsional angles (°) are listed [illegible]ructures:-

(I) $Re_2(CO)_9(CNBu^t)$

(II) $Re_2(CO)_8(CNC_6H_3Me_2\text{-}2,6)_2$

(III) $Re_2(CO)_7(CNMe)_3$

(IV) $Re_2(CO)_6(CNC_6H_3Me_2\text{-}2,6)_4$

(V) $Mn_2(CO)_8(CNBu^t)_2$

(VI) $MN_2(CO)_6(CNC_6H_3Me_2\text{-}2,6)_4$

(VII) diax[$Re_2(CO)_8(PMe_2Ph)_2$]

Molecular Mechanics Calculations

In ch XIV, the results of the X-ray crystal structure determinations of a series of dirhenium carbony_-isonitrile complexes viz. $Re_2(CO)_9(CNBu^t)$ (I), $Re_2(CO)_8(CNC_6H_3Me_2\text{-}2,6)_2$ (II) $Re_2(CO)_7(CNMe)_3$ (III) and $Re_2(CO)_6(CNC_6H_3Me_2\text{-}2,6)_4$ (IV), were presented. In order to quantify the relative importance of the various steric and electronic factors in these structures, molecular mechanics calculations were performed on the complexes (I) - (IV).

The molecular mechanics calculations were carried out using the Energy Minimization Program bMPMDS[285], written by M.I.J. Haneef, and based on the molecular mechanics program of White[286]. The force field used was based on that developed by Koolman et al[287]. (see equation I)

$$E_{total} = \sum_{bonds} K_r(r-r_{eq})^2 + \sum_{angles} K_\theta(\theta-\theta_{eq}) + \sum_{dihedrals} \frac{V_n}{2}[1 + \cos(n\phi-\gamma)]$$
$$+ \sum_{i<j} \frac{A_{ij}}{R_{ij}^{12}} - \frac{B_{ij}}{R_{ij}^{6}} + \frac{q_i q_j}{\varepsilon R_{ij}} \qquad (I)$$

The sources of the force field parameters are discussed below.

(a) Non-bonded parameters

The non-bonded parameters were based on the Lennard-Jones potential (see equation II).

$$V(r) = \frac{A}{r^{12}} - \frac{B}{r^6}$$
$$\text{where } A = \sqrt{\varepsilon^*}\,(2r^*)^6 \qquad (II)$$
$$\text{and } B = \sqrt{\varepsilon^*}\,(2r^*)^3$$

r^* is the van der Waals minimum, and ε^* the van der Waals well depth (see Figure E.1).

Figure E.1. Plot of V(r) against r, showing r^* and ε^*.

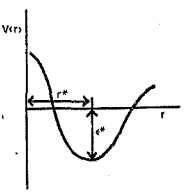

Table E.1 : Values of the force field parameters used in the calculations.

Table E2 : Observed and calulated Re-Re bond lengths for the $Re_2(CO)_{10-n}(CNR)_n$ (n = 0-4) structures.

Structure	Re-Re bond length (Å) Crystal Structure	Calculated
$Re_2(CO)_{10}$	3.041(1)	3.041
$Re_2(CO)_9(CNBu^t)$ (I)	3.048(1)	3.039
$Re_2(CO)_8(CNC_6H_3Me_2\text{-}2,6)_2$ (II)	3.047(1)	3.048
$Re_2(CO)_7(CNMe)_3$ (III)	3.049(1)	3.048
$Re_2(CO)_6(CNC_6H_3Me_2\text{-}2,6)_4$ (IV)	3.081(2)	3.051

The calculated results indicate a slight increase in the Re-Re bond length down the series $Re_2(CO)_{10-n}(CNR)_n$ (n = 1-4), but this effect is not as large as might be expected from the crystal structure data. Hence the role of non-bonded interactions, or steric effects, which might be expected to increase the Re-Re bond length, is not the dominant factor in these structures. The differences between the crystallographic Re-Re bond distance, and the calculated values, can be ascribed to electronic effects which are not adequately modelled by using the force field for the parent $Re_2(CO)_{10}$. In particular, replacing carbonyls by isonitriles, which are poorer π-acceptors[63], would be expected to cause a weakening, and hence a lengthening, of the Re-Re bond. Hence electronic i.e. bonding interactions, rather than steric effects i.e. non-bonded interactions, would appear to be the dominant factor influencing the length of the Re-Re bond in the $Re_2(CO)_{10-n}(CNR)_n$ structures.

The values of r* and ε* for the C,O and N atoms were obtained from Kollman[287]. For Re, the r* value was taken as the shortest Re-Re distance in rhenium metal[288]. The values of r* and ε* used in the calculations are given in Table E.1.1.

(b) Bond length and bond angle parameters.

The values for the equilibrium bond length r_{eq}, and bond angle θ_{eq}, were obtained from X-ray crystal structures of $Re_2(CO)_{10}$[158], and $Re_2(CO)_{10-n}(CNR)_n$ (ch XIV). For the parent compound, $Re_2(CO)_{10}$, the Re-Re equilibrium bond distance was adjusted until the observed structure of $Re_2(CO)_{10}$[158] was reproduced (K_r = 118 kcal mol $\AA^2$). This value of r_{eq} (Re-Re) (3.048$\AA$) was then used in the subsequent calculations for the $Re_2(CO)_{10-n}(CNR)_n$ (n = 1-4) derivatives. The values of r_{eq} and θ_{eq} used in the calculations are given in Tables E.1.2 and E.1.3 respectively.

(c) Force constants.

The bond and angle force constants, K_r and K_θ, were obtained from Infrared[146b] and Raman[147b] Spectroscopic studies on $Re_2(CO)_{10}$. The value used for the force constant for the Re-Re bond was 118 kcal/mol $\AA^2$, obtained from the Raman study of $Re_2(CO)_{10}$ by Spiro et al[147b]. The values of the force constants K_r and K_θ used in the calculations are given in Tables E.1.2 and E.1.3 respectively.

The force field parameters were established by an analysis of the parent $Re_2(CO)_{10}$ structure, the X-ray crystal structure of which has been reported[158]. These force field parameters were then kept constant for the subsequent calculations on the derived $Re_2(CO)_{10-n}(CNR)_n$ (n = 1-4) structures.

Results and discussion.

An analysis of the results revealed a variation in the Re-Re bond length. The values of the bond angles and the other bond lengths did not change significantly. Table E.2 below shows the calculated Re-Re bond lengths, compared to the crystal structure values.

Structure Factor Tables

Code name	(no. of pages)	Structure	Pages
LS2H	(9)	$(\eta^5C_5H_5CO_2Me)Cr(CO)_2(CNBu^t)$	1-9
CPMN	(4)	$(\eta^5C_5H_5)Mn(CO)_2(CNBu^t)$	10-13
FEME	(6)	$Fe(CO)_3(CNMe)_2$	14-15
RECO	(8)	$Re_2(CO)_9(CNBu^t)$ (I)	20-27
REX2	(20)	$Re_2(CO)_8(CNC_6H_3Me_2\text{-}2,6)_2$ (II)	28-47
REM3	(15)	$Re_2(CO)_7(CNMe)_3$ (III)	48-62
REX4	(13)	$Re_2(CO)_6(CNC_6H_3Me\text{-}2,6)_4$ (IV)	63-75
MNTB	(16)	$Mn_2(CO)_8(CNBu^t)_2$ (V)	76-91
MNXY	(7)	$Mn_2(CO)_6(CNC_6H_3Me_2\text{-}2,6)_4$ (VI)	92-98
REP2	(7)	diax-$[Re_2(CO)_8(PMe_2Ph)_2]$ (VII)	99-105
