WITWATERSRAND,
JOHANNESBURG

Developing an advanced reactor model for complex, non-ideal reactors

Prepared by

Ruth Stephenson Elfick

A thesis submitted to the Faculty of Engineering and the Built Environment, University of the Witwatersrand, in fulfilment of the requirements for the degree of Doctor of Philosophy.

Johannesburg 2022

Declaration

I declare that this thesis is my own unaided work. It is being submitted for the degree of Doctor of Philosophy to the University of the Witwatersrand, Johannesburg. It has not been submitted before for any degree or examination to any other University.

Ruth Jane Stephenson

25 January 2022

Summary

Constructed wetlands are a low cost and low maintenance technology which can be used for treating wastewater of various types, and in a water scarce country, such as South Africa, have the potential to be used in a variety of contexts. However, to use this technology as an effective form of wastewater treatment, accurate modelling of both the kinetic and hydraulic behaviour is required. Work has been done to improve the kinetic modelling of constructed wetlands. Kinetic modelling techniques rely on reaction time, but reaction time is a function of the hydraulic behaviour of the system. If the reaction time is quantified incorrectly, a kinetic model will not produce accurate results, regardless of how detailed and comprehensive it may be. It cannot be said that reaction time relies only on the hydraulic behaviour of the system and the importance of mixing and local concentration must not be forgotten.Accordingly, this study investigated the development and use of two novel hydraulic modelling techniques for use in quantifying the flow behaviour of constructed wetlands. The aim was to combine the residence time distribution techniques with an existing biokinetic model. In this study, two techniques were developed which were based on limitations found in existing techniques, and hydraulic tracer studies were conducted to assess the applicability of the techniques for use in constructed wetlands.

The first technique was based on the method-of-moments technique, used in chemical engineering for reactor design, and in this technique, it was assumed that the flow through a system could be divided into sections. By determining the hydraulic parameters of each of the sections, the hydraulic behaviour could be investigated in more detail and the data obtained from the study could be used with an existing biokinetic model. Impulse-response tracer tests were conducted on two systems, vertical flow columns and a horizontal sub-surface flow constructed wetland. It was found that the data from these studies could be used in investigating the hydraulic behaviour of the system and could be combined with first-order rate kinetics.

The second technique aimed to address the environmental impact of tracer studies on water bodies. Tracer studies require the use of a conservative tracer, but the conservative nature of the tracer means that it persists in the environment long after the studies are complete. In this study the use of a non-conservative tracer was investigated. Step-change tracer studies were conducted on a horizontal sub-surface flow constructed wetland using a conservative tracer (uranine) and a non-conservative tracer (benzoate). The response curves of the two tracers were compared and the advective-dispersive solute transport equation, along with a non-linear least-

squares analysis, was used to determine the hydrodynamic dispersion, retardation factor and decay of each tracer. These transport parameters were used to determine if it was possible to relate the non-conservative tracer response curve with the conservative tracer response curve in such a way that the hydraulic parameters, which quantify flow behaviour, were the same. This technique was found to be most accurate for mean residence time.

Acknowledgements

I would like to thank the following people, without whom I would not have been able to conduct this research, and without whom I would not have made it through my PhD.

- To my supervisors, Prof Craig Sheridan and Dr Uwe Kappelmeyer: Thank you for your insight and guidance. This endeavour would not have been possible without your probing questions or enthusiasm for the research.
- To Karin Tonderski: Thank you for your support, guidance and kindness.
- Thank you to the technical teams at Hemholtz Centre for Environmental Research and at the University of the Witwatersrand Chemical engineering department, for your time, effort and constant willingness to aid me in my research.
- Thank you to Tamlyn Sasha Naidu, for your witty commentary, constant wisdom and support; I could not have asked for a better person to go through this with.
- To my family, thank you for your constant love, patience and many hugs. A special thank you to my grandfather Wolter, who is as inspiring a person as he is an academic. And to my darling mom for many supportive hours spent on the phone.
- And most importantly, to Gareth, my husband, for always being there. I would not have been able to achieve this without you by my side. Now let's celebrate!

Y_{FB}	Yield coefficient for fermenting bacteria	g COD_{BM}/g COD_{SF}
Y_H	Yield coefficient for heterotrophic bacteria	g COD_{BM}/g COD_{SF}
Y_{SOB}	Yield coefficient for sulphide oxidizing bacteria	g COD_{BM}/g S
α_l	Mechanical dispersion in the longitudinal direction	m
$\alpha_{l,benzoate}$	Mechanical dispersion of benzoate in the longitudinal direction	m
$\alpha_{l,uranine}$	Mechanical dispersion of uranine in the longitudinal direction	m
α_t	Mechanical dispersion in the transversal direction	m
$\alpha_{t,benzoate}$	Mechanical dispersion of benzoate in the transversal direction	m
$\alpha_{t,uranine}$	Mechanical dispersion of benzoate in the transversal direction	m
σ^2	Variance	$hour^2$
μ	First-order decay coefficient	1/hour
μ_A	maximum aerobic growth rate on SNH	1/d
μ_{AMB}	maximum aerobic growth rate for XAMB	1/d
μ_h	maximum aerobic growth rate on CR	1/d
η_h	Correction factor for hydrolysis by fermenting bacteria	(-)
φ	Zero-order production constant	(-)
γ	Fraction of area under the Impulse-response curve	(-)
λ	Hydraulic efficiency	(-)
ρ_b	Bulk density as SG	(-)
ε	Void fraction	(-)
θ_w	Water content	(-)
θ_r	Residual water content	(-)
θ_s	Saturated water content	(-)

Chapter 1: Introduction

South Africa is a water-scarce country which means that there is not enough of this precious resource to support the needs of both humans and the ecosystem (Bond *et al.*, 2019). Even though water is a renewable resource, there are challenges that relate to both the supply and quality of water (Hedden and Cilliers, 2014). In theory, South Africa treats about 60% of its wastewater, but with a significant number of the existing treatment facilities in poor condition, the actual number could be much lower (Donnefield, 2019). A multi-pronged approach which includes improvements in current wastewater treatment systems, the development of new solutions, and the reduction of water use, is required to remedy the situation.

Developing infrastructure which allows for easy and reliable access to clean water in rural communities is one of the challenges in the South African context (Majuru, Jagals and Hunter, 2012). Constructed wetlands are a treatment technology which have the potential to reduce the contamination instances posed by sewage which will assist towards addressing this issue. These systems are low cost and low maintenance when compared to conventional wastewater treatment technologies (Wu *et al.*, 2015). Constructed wetlands can handle varying loads, promote water reuse and recycling, and have minimal energy requirements (Gu *et al.*, 2017). For these reasons their applicability is being explored in South Africa (Ochieng, Seanego and Nkwonta, 2010).

To make use of constructed wetlands as an effective form of wastewater treatment, design and modelling are required to ensure optimal construction and implementation. The original constructed wetland models developed were considered 'black-box' models which relied on empirical correlations between inlet and outlet concentrations (J. L G Kumar and Zhao, 2011), but recently modelling has advanced to mechanistic and process-based models (Meyer *et al.*, 2015). Of utmost importance in the modelling of constructed wetlands is the accurate modelling of the hydraulic behaviour of the system (Zahraeifard and Deng, 2011).

The hydraulic behaviour of constructed wetlands has been simplified to plug flow by many researchers (Werner and Kadlec, 2000). Ideal plug flow implies that all fluid particles spend the same amount of time in the system. However, there are multiple features of a constructed wetland that prevent ideal plug flow. The heterogeneous nature of the sub-surface media of constructed wetlands, changing root structure of macrophytes, biofilm growth, and clogging due to suspended solids, all contribute to a variation in flow resistance in the constructed

wetland. This variation in resistance leads to a variation in the flow velocity profiles and as a result, fluid particles do not all spend the same amount of time in the system. This leads to non-ideal plug flow behaviour and a distribution of residence times within the constructed wetland.

To gain an understanding of the hydraulic behaviour of a constructed wetland, residence time distribution (RTD) studies are conducted (Kadlec, 2007). The data from these studies are used to determine hydraulic parameters such as the mean residence time. The mean residence time is the average amount of time that the fluid particles have spent in the system and is supposed to represent the non-ideal hydraulic behaviour resulting from the residence time distribution (Fogler, 2006). All kinetic models require some representation of the hydraulic behaviour of a constructed wetland and it is common for the mean residence time from a tracer study to be used (Kadlec, 2007). However, a single value is not enough to accurately represent the non-ideal hydraulic nature of constructed wetlands and this can lead to the under-sizing and inaccurate design of the systems (Fontes Lima and Zaiat, 2012).

There are still limitations in the understanding and modelling of the hydraulic behaviour of constructed wetlands. In this thesis, two techniques are presented which aim to address some of these limitations. The first technique presented is an adapted method-of-moments technique which makes assumptions about the multiple flow paths and velocities in a constructed wetland, and the extent of pollutant degradation in each of these flow paths. Effort is made to combine this technique which an existing and established multi-component biokinetic model, the Constructed Wetlands Model No.1 (CWM1).

The second technique which is described in this thesis has been developed to use the data from tracer studies conducted with non-conservative tracers, such as benzoate. The aim of this technique is to address the limitations of conservative tracers when conducting tracer studies on constructed wetlands. Tracer studies require the use of a soluble and conservative tracer to be injected into the constructed wetland (Chazarenc, Merlin and Gonthier, 2003). The conservative nature of the tracer implies that it is not degraded or retained in the system either through adsorption, photodegradation or biodegradation, to name a few mechanisms (Cucco and Umgiesser, 2006). The long-term effects of the tracers on living organisms in constructed wetlands are still relatively unknown, and disposal of tracer (if possible) can be costly. The use of biodegradable chemicals, such as benzoate, to be used as a tracer has not been investigated previously. A biodegradable chemical would reduce the negative impact of the tracer studies

on the environment in which the study is being conducted, as it would not remain there permanently.

1.1 Research Objectives

a) To develop an advanced, novel residence time distribution technique in order to improve the accuracy of the measurement of constructed wetland hydraulics.

b) To apply the technique to the International Water Association's constructed wetland model No.1 (CWM1) to improve the accuracy of the predicted output concentrations.

c) To modify the matrices of stochiometric coefficients and rate laws given in CWM1 to include a residence time distribution function.

d) To calibrate the model on a small-scale indoor reactor.

e) To validate the model on an established large-scale outdoor wetland.

1.2 Problem Statement

Various biokinetic models have been developed to predict the output concentrations of a constructed wetland, but these models do not necessarily account for the non-ideal plug flow behaviour and residence time distribution of the wetland. Attempts to combine hydraulic reactor modelling and biokinetic modelling have either assumed reactor types with deviations or require highly advanced numerical modelling skills and technologies.

1.3 Thesis Structure

This thesis has been divided into 8 chapters. An introduction and analysis of literature make up the first two chapters. The next four chapters each addresses a specific research objective.

In Chapter 3, the methods and materials used in the development of two residence time distribution techniques are detailed.

In Chapter 4, two residence time distribution techniques are presented. The first is based on the method-of-moments technique and the second is based on the advective-dispersive transport equation.

In Chapter 5, a combination of the two residence time distribution techniques with an existing and established biokinetic model, the Constructed Wetlands Model N°1, is presented.

In Chapter 6, the methods used to linearise the reaction rates of the Constructed Wetlands Model N°1, to be used with the adapted method-of-moments technique, are presented.

In Chapter 7, the validation of the technique based on the advective-dispersive transport equation on a small-scale constructed wetland is presented. The validation of the adapted method-of-moments technique on gravel filled columns and a small-scale constructed wetland is also given.

In Chapter 8, the work is discussed, potential ramifications for constructed wetland design are presented, and concluding remarks are made.

Chapter 2: Literature review

Contents of this chapter have been published in The Journal of Water Process Engineering (Stephenson, R. and Sheridan, C. (2021) 'Review of experimental procedures and modelling techniques for flow behaviour and their relation to residence time in constructed wetlands', *Journal of Water Process Engineering*. Elsevier Ltd, 41(February), p. 102044. doi: 10.1016/j.jwpe.2021.102044)

2.1 The Historical Context and Use of Constructed Wetlands

Constructed wetlands (CWs) are systems which make use of the same process as natural wetlands and have been designed and placed specifically for wastewater treatment (Brix, 1994). Various physical, biological, and chemical processes take place simultaneously and these all influence one another. It is the combination of these processes that leads to a reduction in contaminant load of wastewater. CWs consist of 3 main components, the packing medium (such as soil or gravel), macrophytes, and a multitude of microorganisms.

For as long as humans have been discharging wastewater, wetlands have played a role in the treatment of this wastewater. The first documented use of CWs was in 1904 in a report to the Hornsby Literary Institute in NSW, Australia (Brix, 1994). Not much further happened until the 1950s, when, in Germany, K. Seidel was the first to investigate the use of CWs to treat wastewater (Seidel, 1961). Seidel continued investigations into the 1960s into the treatment of different waste streams including phenol, dairy, and livestock waste streams (Kadlec and Wallace, 2009). Throughout the 1970s and 1980s CWs were adopted around Europe, including Denmark, France, the United Kingdom, and the Netherlands. During this time CWs were used almost exclusively for domestic and municipal water treatment but from the 1990s these systems were used for a much wider range of wastewater treatment (Vymazal, 2005). By this time, CWs had become the preferred method of wastewater treatment for decentralised systems such as small villages. It was during the 1970s that the use of CWs began to emerge in the USA, treating streams such as wildlife habitat discharge (1973), industrial waters (1975), and process waters (1975). The use of surface flow CWs was more commonly adopted in the USA while sub-surface flow CWs were the predominantly used CW in Europe (Vymazal, 2010). The use of CWs was adapted on the African continent during the late 1980s and 1990s with the applications including agricultural, mining, industrial, and domestic wastewater treatment (Kadlec and Wallace, 2009).

2.2 Advantages and Disadvantages of Constructed Wetlands

Some of the advantages of CWs are that they can provide on-site treatment, they are pleasing to the eye, and provide a habitat for amphibians, birds, and plants. CWs are low-cost systems that require minimal operation and maintenance (Wu *et al.*, 2015). These systems can handle varying loads, promote water reuse and recycling, and have minimal energy requirements (Gu *et al.*, 2017). This makes CWs an attractive option in water scarce, rural areas, as these systems are able to address the need for clean water without incurring a large capital cost or requiring large amounts of energy and an expert to run them.

However, there are some disadvantages of these systems. The perception of low maintenance means that it many cases no maintenance is done and as a result, in the long term, the system can fail. They are also potentially a habitat for insects, such as mosquitos, which can bring other problems and diseases including malaria and yellow fever (Bondurant, 2010). Owing to the need for microbial communities to be established, CWs may also have a lengthy start-up time. Nitrogen removal is another limitation of these systems, as different redox and aeration conditions are required to remove the different forms of nitrogen, and so only complex CW configurations achieve adequate nitrogen removal (Vymazal, 2013). Some wetland plants are sensitive to high COD levels and clogging is a major operational problem of CWs. They are also land intensive and have a larger foot print than more elevated systems (Wu *et al.*, 2014).

One of the biggest barriers to CWs being widely used as a form of wastewater treatment is the lack of proper design protocols. Many different configurations and recommendations exists, but because of the lack of detailed understanding of the combination of microbial processes that break down wastewater contaminants, the interrelatedness of these processes with other physical and chemical processes, and the changing and complex hydraulic nature of CWs, setting design protocols has not yet been achieved (Sheridan, 2012; Wu *et al.*, 2015).

2.3 Classification of Constructed Wetlands

CWs can be classified according to various characteristics. One of the most common characterisations is based on the fluid flow of the wetland. Flow can be characterised as being below the surface or on the surface. Free water surface flow CWs are primarily horizontal flow while sub-surface flow wetlands can either have horizontal flow, vertical flow, or both. The other characteristic used as a basis for classification of CWs is the type of macrophyte used in

the system: submerged, emergent, or free floating. The different configurations have their advantages and disadvantages, and the choice of wetland should be guided by the treatment and design requirements. Figure 2.1 gives a breakdown of the classification of CWs.

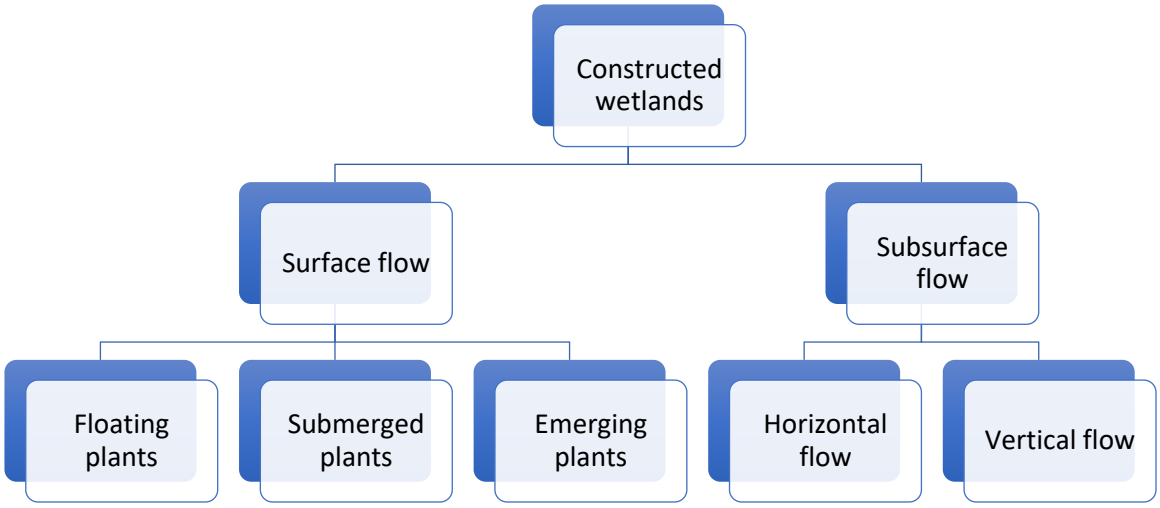

***Figure 2.1**: Breakdown of the classification of CWs ,adapted from (Kadlec and Wallace, 2009)*

2.3.1 Free Water Surface Wetlands

Free water surface (FWS) wetlands consist of areas of open water with emergent and floating plants, and commonly have a water level of 0.4 m (Langergraber, 2008). This configuration tends to look very similar to a natural wetland although liners, dikes and berms can be used to control the flow through the system (Kadlec and Wallace, 2009). Apart from water treatment, FWS wetlands have additional benefits, such as a habitat for amphibious and bird wildlife (Kadlec, 2009). When treating urban, agricultural, and industrial stormwaters, FWS wetlands are the most common choice among the configurations owing to their ability to deal with pulse flow and changing water levels. They are also often used for mine water treatment, groundwater remediation, and leachate treatment. Figure 2.2 is an example of a FWS CW.

One of the disadvantages of FWS wetlands is that the exposed water surface, and typically low flow rates, make these systems susceptible to insect infestations and the release of odours from the polluted water, which are difficult to control due to lack of covering (Bondurant, 2010; Leverenz *et al.*, 2010). Because of the exposed water surface, water tends to flow over the bed

and therefore there is limited contact with the dense microbial matrix, resulting in lower degradation potentials. Other disadvantages of FWS wetlands relate to the systems' response to temperature: these systems are prone to excessive evapotranspiration in summer because of the lack of covering (Kivaisi, 2001); Kadlec *et al.*, 2009). Note that during the winter months there is a decrease in nitrogen removal efficiency because the majority of the removal is dependent on biological activity, which requires warmer temperatures (Kadlec, 2009). FWS CWs can be used as stand-alone systems or as part of a multi-step process. If part of a multi-step process, then the FWS CW is typically a tertiary treatment step after sedimentation and biological treatment processes (Wallace and Knight, 2006).

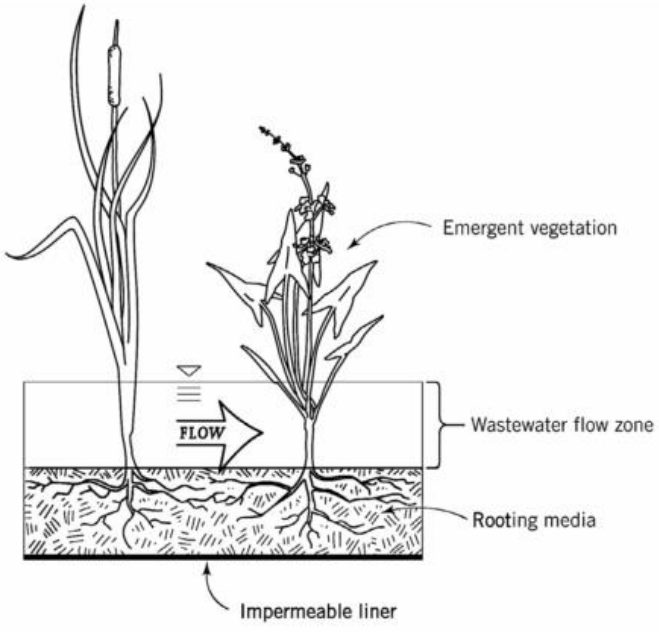

***Figure 2.2**: Free water surface constructed wetland (Kadlec and Wallace, 2009)*

2.3.2 Horizontal Sub-surface Flow Constructed Wetlands

Horizontal sub-surface flow (HSSF) wetlands consist of beds of a packing material, commonly soil or gravel, planted with vegetation. Water flows below the surface of the bed and comes into contact with biofilms, plant roots, and rhizomes which facilitates pollutant removal (Vymazal, 2009; García *et al.*, 2010). Typically, a HSSF wetland consists of inlet and outlet piping, a liner, berms, and emerging vegetation (Kadlec and Wallace, 2009). Water enters through a single inlet or inlet distribution network and flows horizontally along the length of the wetlands to the outlet (Rios *et al.*, 2009). Bed depth is typically between 0.6 m and 1.0 m and the bottom of the bed is sloped downwards to prevent water from flowing across the surface of the system (Haberl *et al.*, 2003). Due to the low exposure of the treatment water to the open

air, compacted soil, and macrophyte covering, there is limited oxygen transfer in HSSF wetlands and so oxidation of ammonia as well as other aerobic processes is minimal (Camacho *et al.*, 2007). Figure 2.3 displays the various components of a HSSF CW.

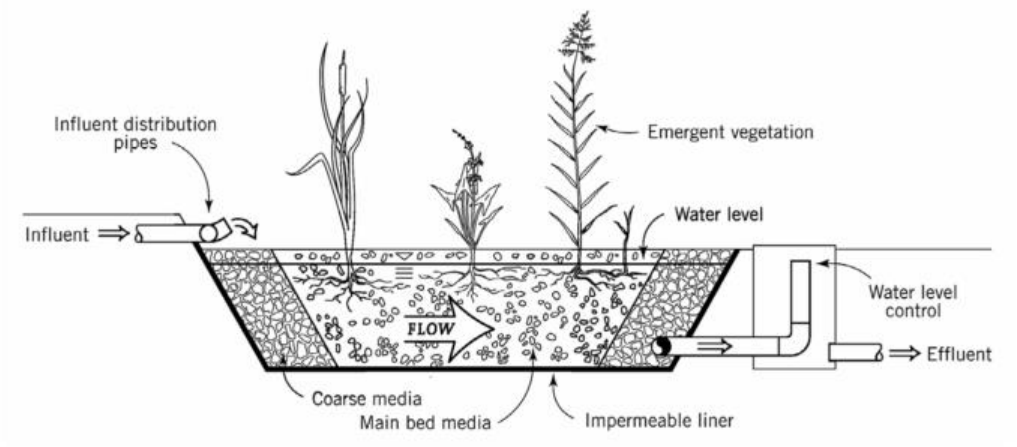

***Figure 2.3**: Horizontal sub-surface flow constructed wetland (Kadlec and Wallace, 2009)*

2.3.3 Vertical Flow Sub-surface Flow Constructed Wetlands

In vertical flow (VF) wetlands, water is distributed along the surface of the bed and percolates vertically downward through the porous medium and plant roots to a drainage network (Lavrova and Koumanova, 2010). These systems are an attractive alternative which require less surface area than horizontal sub-surface flow CWs (Kadlec and Wallace, 2009). The intermittent loading means that air is sucked into the CW as water levels drop between loading cycles and is then displaced by water once the CW is loaded again. Because of this, aerobic processes are more dominant in VF wetlands than HSSF wetlands (Langergraber, 2008). The consequence is that VF wetlands cycle between aerobic and anaerobic processes. The gravitation effect of the flow in vertical flow CWs promotes settling and sedimentation, this combined with aerobic conditions enhances high rates of biological degradation (Saeed and Sun, 2012). VF wetlands are used to treat landfill leachates and food processing wastewater, both of which have a high ammonia content. Biosolids dewatering is also a common use of VF wetlands (Kadlec and Wallace, 2009). One of the drawbacks of the VF CWs is the inability to remove phosphorus from wastewater due to insufficient binding capacity of the available granular media (Brix and Arias, 2005; Prochaska and Zouboulis, 2006). Figure 2.4 displays a schematic of a VF CW.

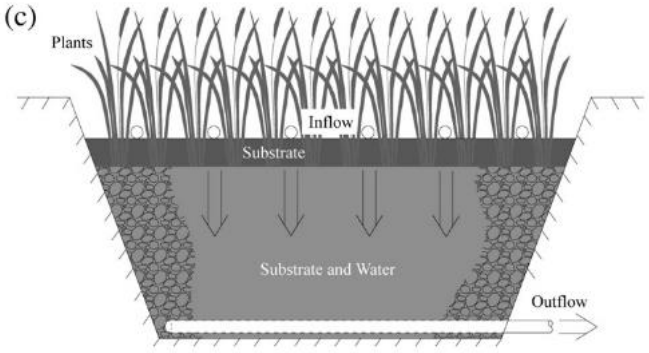

***Figure 2.4**: Vertical sub-surface flow constructed wetland (Li et al., 2014)*

2.3.4 Hybrid Systems

It is also possible to create a hybrid CW system by combining two or more wetlands of different types in order to make use of the advantages of the different systems. Many combinations of hybrid CWs exist but the most common one is a VF-HF hybrid system (Vymazal, 2013). Hybrid CWs are mostly used to enhance total nitrogen removal because different types of CWs provide different redox conditions which are suitable for nitrification and denitrification (Vymazal, 2011a). Hybrid wetlands have mainly been used for sewage treatment (Vymazal, 2013) but other types of wastewater treated include landfill leachate (Bulc, 2006), domestic wastewater (Jehawi *et al.*, 2020), secondary effluent (Bang *et al.*, 2019), swine wastewater (Ren, Wang and Zhao, 2020), winery effluent (Serrano *et al.*, 2011), and cooling tower water (Wagner *et al.*, 2020).

2.3.5 Classification by Plant type

Plants are a vital component in CWs as they aid the removal of contaminants from wastewater in various ways (Brix, 1987; Wu *et al.*, 2011). There are 3 categories in the classification of CW macrophytes: free-floating, submerged, and emergent (Dhote and Dixit, 2009; Bakker *et al.*, 2013). Free-floating macrophytes float on the surface of the water, with only their roots submerged (Van De Moortel *et al.*, 2010; Headley and Tanner, 2012). The two most commonly used free-floating macrophytes in CWs are *Eichhornia crassipes* (water hyacinth) and *Pistia stratiotes* (water lettuce) (Marchand *et al.*, 2010; Mufarrege, Hadad and Maine, 2010). In Figure 2.5 an illustration of a free-floating macrophyte CW can be found. Submerged macrophytes have their entire structure below the water surface and so the whole plant plays a role in wastewater treatment (Dhote and Dixit, 2009). *Potamogeton crispus* and *Littorella uniflora* are two of the most regularly used submerged macrophytes in CWs (Dordio and

Carvalho, 2013; Zhao *et al.*, 2014). An illustration of submerged macrophytes in a CW can be found in Figure 2.6. Emergent macrophytes have their roots in the soil but emerge above the surface of the water to different heights. The most commonly emerged macrophyte used on CWs is *Phragmites australis* (Common reed) (Vymazal, 2011b) while *Typha latiofolia* and *Phragmites carka* are also regularly used (Li *et al.*, 2013). An illustration of an emergent macrophyte CW can be found in Figure 2.7. While all three plant-classified types of wetlands are possible for surface flow CWs, sub-surface flow CWs have only emergent macrophytes, as the surface of the water is covered by the wetland medium, such as gravel.

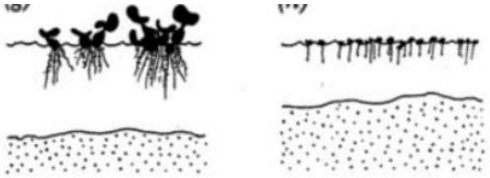

Figure 2.5*: Examples of free-floating macrophytes used in constructed wetlands adapted from (Headley and Tanner, 2012)*

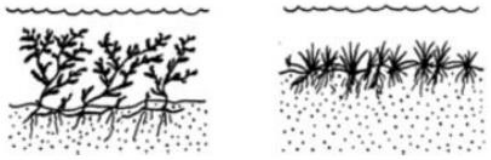

***Figure 2.6**: Examples of submerged macrophytes used in constructed wetlands adapted from (Headley and Tanner, 2012)*

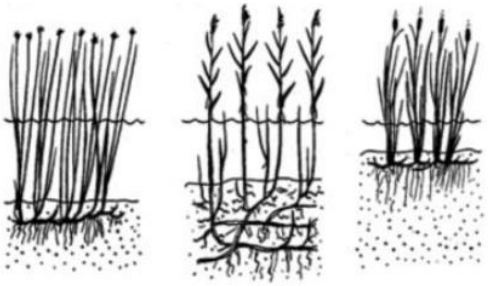

***Figure 2.7**: Examples of emergent macrophytes used in constructed wetland adapted from (Headley and Tanner, 2012)*

2.4 Waste Streams Treated by Constructed Wetlands

Early uses of CWs were mainly for the treatment of domestic and industrial wastewater on a small scale and this area of application continues to grow. The range of treatment applications has increased to include agricultural, industrial, and stormwater runoff (Vymazal, 2009). In the treatment of municipal wastewater, wetlands are used as secondary treatment for small communities or as add-ons for existing treatment units (Wallace and Knight, 2006). Examples of the different types of wastewater treated by CWs include landfill leachate (Nivala *et al.*, 2007; Wojciechowska, 2017; Yi *et al.*, 2017; Bakhshoodeh *et al.*, 2020), petroleum refinery waste (Aslam *et al.*, 2007; Jain *et al.*, 2020), dairy wastewater (Pelissari *et al.*, 2014; Adhikari, Harrigan and Reinhold, 2015; Schierano *et al.*, 2020), winery effluent (Serrano *et al.*, 2011; Sheridan, Glasser and Hildebrandt, 2014; Rozema, Rozema and Zheng, 2016; Flores *et al.*, 2019), and acid mine drainage (Pat-Espadas *et al.*, 2018; Singh and Chakraborty, 2020).

2.5 Mechanisms for Contaminant Removal in Constructed Wetlands

2.5.1 Mechanisms for Organic Matter Removal

Organic matter (OM) in wastewater typically takes two forms, particulate organic matter and dissolved organic matter. The breakdown of the two forms occurs via different processes and

the pathways for both of these are discussed here. Organic matter present in wetlands has two sources, an external source and an internal source. The external source is from the influent wastewater, while the internal source is from the macrophytes in the system called root exudates (Headley and Tanner, 2012).

Particulate organic matter

CWs are often a secondary step in the wastewater treatment process and so a large portion of the total suspended solids (TSS) (a category into which particulate OM falls) have already been removed (Vymazal, 2011a). Influent particulate OM is removed by the physical processes of sedimentation and filtration (Vymazal and Kröpfelová, 2008). This particulate OM then either accumulates or disintegrates and undergoes hydrolysis. This process generates dissolved OM which is degraded through a variety of other pathways. The build-up of particulate organic matter contributes significantly to clogging, which is the most common operational problem of CWs and is known to decrease the residence time (Knowles *et al.*, 2011). The removal rates of influent TSS in SSF CWs are usually very high (>90%) (García *et al.*, 2010).

Dissolved organic matter

The decomposition of dissolved OM can take place under aerobic, anoxic and anaerobic conditions(Saeed and Sun, 2012). Under aerobic conditions oxygen is the final electron acceptor. Oxygen can enter the system through three pathways: with the influent water, through surface reaeration, and through plant root release. In horizontal sub-surface flow CWs, the oxygen entering the wetland from these three processes is not considered enough to maintain aerobic conditions. Vertical flow CWs experience more aerobic conditions because they are typically operated under intermittent loading and resting periods, which promotes the physical reaeration of intergranular spaces (Langergraber and Simunek, 2005). Aerobic degradation of organic matter is given in Equation 2.1 and is performed by heterotrophic bacteria (Vymazal and Kröpfelová, 2008).

$$C_6H_{12}O_6 + 6O_2 \rightarrow 6CO_2 + 6H_2O + 12e^- + energy \quad (2.1)$$

Under anoxic conditions, OM is degraded by bacteria which use nitrate or nitrite as the final electron acceptor, as well as oxygen. In cases where the dissolved oxygen is depleted, anaerobic degradation takes place. Anaerobic conditions allow for the development of many different bacterial groups, intermediate steps, and alternative pathways (García *et al.*, 2010). There are

multiple steps in the process of anaerobic digestion, starting with the conversion of complex soluble polymers into monomers and amino acids. From there the amino acids are fermented to produce fatty acids, alcohols, hydrogen, methane, and carbon dioxide. The fatty acids are subsequently converted into carbon dioxide, water, and hydrogen sulfide by sulfate-reducing bacteria. This process follows the reaction given in Equation 2.2 (Gujer and Zehnder, 1983):

$$CH_3COOH + {SO_4}^{2-} \rightarrow 2CO_2 + 2H_2O + S^{2-} \quad (2.2)$$

Methanogenic bacteria also convert fatty acids, carbon dioxide, and hydrogen into methane by the two reaction steps given in Equation 2.3 and Equation 2.4 (Vymazal and Kröpfelová, 2008).

$$CH_3COOH + 4H_2 \rightarrow 2CH_4 + 2H_2O \quad (2.3)$$

$$4H_2 + CO_2 \rightarrow 2CH_4 + 2H_2O \quad (2.4)$$

2.5.2 Mechanisms for Nitrogen Cycling

Inorganic nitrogen present in wastewater can take the form of ammonia, nitrite, nitrate, nitrous oxide and elemental nitrogen or nitrogen gas (Deblonde, Cossu-Leguille and Hartemann, 2011). Organic nitrogen pollutants include aromatics and amino acids (Rosal *et al.*, 2010). CWs were proposed as a tool for the removal of nitrogen from agricultural wastewater in the 1990s, with surface flow constricted wetlands being the most commonly used type of wetland for this use (Mitsch, 1992; Vymazal *et al.*, 2020). Nitrogen transformation occurs through a variety of processes which are discussed below.

Ammonia volatilisation

Ammonia volatilisation is an equilibrium reaction between ammonium and ammonia and this reaction is pH dependent. At a pH of 9.3 or higher, the removal of nitrogen via ammonia volatilisation is effective, while at less than a pH of 8 this effect is not significant (Reddy, Patrick and Broadbent, 1984). The equilibrium reaction is given below in Equation 2.5.

$$NH_3 + H_2O \rightleftarrows {NH_4}^{+} + OH^{-} \quad (2.5)$$

Ammonia volatilisation rates are typically between 0.27 and 0.5 g N m-2 day-1, and constitute a small portion of the total nitrogen removal in HSSF CWs (Poach, M. *et al.*, 2002).

Ammonification

Ammonification in the process in which organic nitrogen (peptides, proteins and nucleic acids) are transformed into ammonium (Vymazal, 2007; Saeed and Sun, 2012). The rate at which this process takes place is a function of temperature, pH, soil conditions and the carbon : nitrogen ratio in the wetland (Reddy, Patrick and Broadbent, 1984). The optimal pH range for ammonification is between 6.5 and 8.5, while the optimal temperature lies in the range of between 40 ºC and 60 ºC (Vymazal, 1995). This conversion happens via a series of oxidative and reductive deamination reactions (Vymazal, 2007). The oxidative scheme is provided in Equation 2.6 (Savant and De Datta, 1982) and the reductive scheme is provided in Equation 2.7 (Rose, 1976). The oxidative conversion process proceeds much faster than the reductive conversion process (Vymazal, 2007). In HSSF CWs the rate of ammonification is typically higher near the surface of the wetland, where there are higher levels of dissolved oxygen.

$$\text{Amino acids} \rightarrow \text{Imino acids} \rightarrow \text{Keto acids} \rightarrow NH_3 \tag{2.6}$$

$$\text{Amino acids} \rightarrow \text{saturated acids} \rightarrow NH_3 \tag{2.7}$$

Nitrification

Nitrification is defined as the biological oxidation of ammonia to nitrate with nitrite as an intermediate product (Vymazal, 2007). The first step is the conversion of ammonia to nitrite by aerobic bacteria (Equation 2.8) and in the second step, nitrite oxidising bacteria convert the nitrite to nitrate (Equation 2.9) (Vymazal, 2007). The nitrifying bacteria derive energy from the oxidation of ammonia and CO_2 is usually the carbon source (Paul and Clark, 1996).

$$NH_4^+ + 1.5O_2 \rightarrow NO_2^- + 2H^+ + H_2O \tag{2.8}$$

$$NO_2^- + 0.5O_2 \rightarrow NO_3^- \tag{2.9}$$

The rate of nitrification is dependent on temperature, pH value, alkalinity of the water, inorganic C source, moisture, microbial population, and concentrations of ammonium and dissolved oxygen (Vymazal, 1995). Nitrification rates in wetlands were reported to be in the range of 0.01–2.15 g N m^{-2} d^{-1} with the mean value of 0.048 g N m^{-2} d^{-1} (Reddy and D'Angelo, 1997).

Denitrification

Denitrification is most commonly defined as the process in which nitrate is converted into dinitrogen via intermediates nitrite, nitric oxide, and nitrous oxide (Paul and Clark, 1996). The equations for this irreversible reaction can be seen in Equation 2.10 (Hauck, 1984). This process takes place under anaerobic conditions with organic compounds being used by bacteria as a carbon source (Wen *et al.*, 2010) and nitrogen being used as an electron acceptor instead of oxygen (Vymazal, 2007). Denitrification is usually the first process to take place after oxygen has been depleted in the system.

$$6(CH_2O) + 4NO_3^- \rightarrow 6CO_2 + 2N_2 + 6H_2O \qquad (2.10)$$

Factors which influence the rate of denitrification are oxygen concentration, redox potential, presence of denitrifiers, organic matter, nitrate concentration, pH and temperature (Vymazal, 1995, 2007). The optimum pH range lies between 6 and 8, with the process being slow but significant at a pH of 5 and insignificant below a pH of 4 (Paul and Clark, 1996). Rates of denitrification are at a maximum in the temperature range 60°C to 75°C and then they decline rapidly after that (Vymazal, 2007).

Annamox ©

The anaerobic oxidation of ammonium is also possible and understanding of this process is more recent that nitrification. This process takes place via the following reaction (Equation 2.11)

$$NH_4^+ + 1.32NO_2^- + 1.066HCO_3^- + 0.13H^+ \rightarrow$$

$$1.02N_2 + 0.26NO_3^- + 0.066CH_2O_5N_{0.15} + 2.03H_2O \qquad (2.11)$$

Research conducted by Coban et al. (2015) revealed that annamox activity is low in HSSF CWs and as such, does not play a large role in the overall nitrogen transformation process (Coban *et al.*, 2015).

Plant uptake

Two forms of nitrogen are taken up by plants: ammonia and nitrate. This assimilation takes place at its fastest rate during plant growth. Nitrogen uptake by plants is reliant on the plant growth rate and the concentration of nitrogen in the water (García *et al.*, 2010). In order for

this to be a long-term form of nitrogen removal, harvesting of the biomass is required, which can be costly and so this is not considered an extensive process of nitrogen removal (Vymazal, 2007).

Adsorption

Adsorption of ammonium ions onto the surface of the wetland medium is able to remove some nitrogen, but this process is not considered a long-term sink. The amount adsorbed onto the surface is dependent on the concentration of ammonium in the water, the type, nature, and amount of soil organic matter, and the presence of vegetation (Savant and De Datta, 1982; Vymazal, 2007).

2.5.3 Mechanisms for Phosphorus Removal

Phosphorus removal in CWs is achieved mainly through sorption, precipitation, plant uptake (requiring subsequent harvest), and peat/soil accretion. The sorption of phosphorus is limited by the adsorption capacity of the wetland medium, and this capacity increases with clay and mineral content (Prochaska and Zouboulis, 2006). Precipitation takes place when phosphorus reacts with metallic cations such as Fe, Al, Ca or Mg, forming amorphous or poorly crystalline solids (Reddy and D'Angelo, 1997). The removal of phosphorus by plant uptake is fastest during the first phase of plant growth, but thereafter is limited. In order for this removal mechanism to be effective, the plants must be harvested so that the phosphorus is not released back into the system as the plants decay. All three of these mechanisms are saturable (Vymazal, 2007) which means there comes a point when the removal is not dependent on phosphorus concentration. Soil accretion of phosphorus is the dominant long-term sink in CWs. This removal mechanism is only effective in systems with a high generation of biomass and water overlying the sediment. Because of this, it is only FWS CWs with emergent vegetation that are really able to achieved long-term phosphorus removal (Vymazal, 2007).

2.5.4 Mechanisms for Sulphur Removal

Sulfur is an important component in biochemical processes in CWs. There is high sulfur oxidation and reduction in CWs (Baldwin and Mitchell, 2012; Chen *et al.*, 2016). Sulfide is considered the main product of sulfur reduction and has the potential to reduce the treatment efficiencies of CWs as it inhibits ammonium/carbon removal and plant photosynthesis (Chen *et al.*, 2016). Two main pathways are considered for the removal of sulfide: precipitation with

heavy metals, and oxidation (Stein *et al.*, 2007; Wiessner *et al.*, 2010). Both chemical and microbial oxidation of sulfur take place in CWs (Wu *et al.*, 2013).

2.5.5 Mechanisms for Metal Removal

Metal removal in CWs can occur via multiple pathways including sedimentation, filtration, chemical precipitation, adsorption, through interactions with the microbial matrix, and through interactions with the vegetation (Hafeznezami, Kim and Redman, 2012). Multiple factors including pH, plant growth and transpiration rates, redox conditions, and the presence of aerobic and anaerobic bacteria, affect the ability of a CW to remove metals (Hadad, Maine and Bonetto, 2006). Vegetation and sub-surface media facilitate the sedimentation of metals by decreasing water flow rates (Lee and Scholz, 2007). Absorption by plants is also possible for metals such as iron, manganese, zinc, copper, cadmium, and chromium. However, the contribution of plant accumulation to the overall metal removal rate in HSSF CWs is limited (García *et al.*, 2010). Metals such as iron, aluminium, and manganese precipitate out of the water and are deposited in the wetland in the form of oxides or hydroxides (Woulds and Ngwenya, 2004). Adsorption of metal ions onto the substrate surface is an important mechanism for removing metals from wastewater in CWs (Marchand *et al.*, 2010). This step is limited by the adsorption capacity of the wetland substrate and can become saturated. Potassium is a nutrient for plants and is rapidly taken up during plant growth (Bustamante *et al.*, 2011).

2.6 The Design of Constructed Wetlands

CWs are complex systems and thus their design must be carefully considered. There are various factors that need to be investigated in the design of a CW, starting with the type of wastewater to be treated as well as the inlet concentration of contaminants and the required outlet concentrations. The second consideration is the type of CW. As discussed in Section 2.2, the dominant treatment processes that take place in a CW are dependent on the type chosen. Then the site on which the wetland is to be built must be investigated. This will determine many of the physical and biochemical conditions of the wetland. Factors such as climate, geography, soil conditions and potential for run-off water out of the CW are affected by the site and will have an impact on the treatment capacity of the CW. Then there are other considerations to be made, such as the water depth which determines the volume of water to be treated and the effectiveness of the system. The macrophytes used in a CW play a significant role in the

treatment processes. Transpiration, flow resistance, and particulate trapping are all physical processes that take place as a result of the presence of plant life in a wetland. Therefore, the plant type as well as density must be considered. The location and density of plants affects the extent of mixing in the wetland (Guo *et al.*, 2019). The type of matrix is also an important factor. In the original use of CWs, soil with a high clay content was used. This, however, led to recurring clogging problems. In the 1980's, in the United Kingdom, the use of clay was changed to washed gravel, thereby alleviating the clogging problems (Vymazal, 2005). The type of porous material used can include soil, gravel, sand, and slag, to name a few (Kadlec and Wallace, 2009). The inlet and outlet configurations affect the effective volume usage and mixing in the system, with a distributed inlet considered optimum for hydraulic behaviour (Sabokrouhiyeh *et al.*, 2017). Wetland configuration and aspect ratio are also necessary factors to consider in the wetland design. The larger the length to width ratio, the more the system has ideal plug flow behaviour, but resistance to flow increases along the length of the wetland, which can lead to overflow, and larger length to width ratios have higher capital costs (Knight, 1987; Reed, Crites and Middlebrooks, 1995; Persson, 2000).

2.7 The Need for Modelling of Constructed Wetlands

To use CWs as an effective form of wastewater treatment, accurate design and modelling is required. This need has become increasingly evident in the last three decades, as many models have been developed, with varying levels of complexity. The challenge with CW modelling is that the inherent complexity of the CW itself means that the model may require more time or computational power than is available or necessary under the circumstances (Meyer *et al.*, 2015). For the design of CWs, the models developed tend to be simpler and require less computational power than those developed for scientific research, but they may not be as accurate (Meyer *et al.*, 2015). Complex physical, chemical, and biological processes take place simultaneously, and this is layered with the complexity of modelling diffusive flow in wetlands, making it more difficult to model than conventional wastewater treatment processes (Marsili-Libelli and Checchi, 2005).

Meyer et al., (2015) described the following needs for modelling of CWs:

- Describing the phenomena ongoing in a CW (e.g., water flow, adsorption, O_2 transfer).
- Using models as a tool to compare 2 similar systems and their behaviour under different conditions (e.g., effect of loading characteristics, effect of plant species, effect of season, etc.).
- Predicting the performances of a given system (e.g., developing design recommendations).
- Answering "what if?" questions (e.g., over or under loads, etc.).
- Performing system control (especially in case of system intensification like the use of artificial aeration, recycling etc.).

The original CW models developed were considered 'black-box' models which relied on empirical correlations between inlet and outlet concentrations (J. L G Kumar and Zhao, 2011). These techniques relied on a qualitative understanding of what takes place in a CW but limited quantitative estimation of the role that the various processes play in the treatment of wastewater (Rizzo and Langergraber, 2016). Correlations based on surface area, regression, and first-order models were used but these models could only be used for similar systems where the wastewater type, plant type, climate, and porous material are all the same. Inherent in 'black-box' models is an assumption about the flow, typically that there is ideal plug flow in the CW. Given the complexity of these systems and based on research conducted in recent years, it can be said that this assumption does not hold and that these empirical correlation-based models are not adequate to model CWs (J. L G Kumar and Zhao, 2011; Stephenson and Sheridan, 2021). Subsequently, modelling has advanced to mechanistic and process-based models. These models can be divided into two general categories:

1. Models which describe the hydraulic behaviour of the CW in detail but assume simple kinetics or focus on the reactive transport of a single contaminant
2. Models which describe the detailed reactive transport of a single (or multiple) contaminant(s), but assumes simplified or ideal hydraulic behaviour

In both cases some simplifying assumptions have been made, either with regards to reaction kinetics or hydraulic behaviour. In recent years, models have been developed which combine detailed modelling of both hydraulic behaviour and reaction kinetics. These models typically

require extensive computational power, a specific software, and a detailed understanding of numerical modelling.

2.8 Kinetic Modelling of Constructed Wetlands

The rate at which chemical components are converted is referred to as the 'kinetics' of the process (Fogler, 2006). The kinetics of a process are required for the design and sizing of equipment such as reactors (Levenspiel, 1999). The kinetics of processes in CWs are not simple owing to the interrelatedness of individual components and specific reactions. Initial kinetic modelling of CWs was based on quantitative correlations between inlet and outlet concentrations. This was a good starting point but in time proved to be insufficient to describe wetland process and so kinetic models have become more advanced.

2.8.1 Reaction Rate

The reaction rate of a specific component is defined in Equation 2.12. This is the conversion of a specific component with respect to time and is dependent on properties of the reacting materials or micro-organisms. First order rates are linear and have a rate that is proportional to the concentration. These are typically the most commonly found, especially in unsaturated biologically reacting systems. An example of this, for component A, is given in Equation 2.13 Reaction rates can also be an algebraic function, and proportional to concentration to some power of 'n'. Equation 2.14 gives an example of this for component A.

$$r_i = \frac{1}{V}\frac{dN_i}{dt} \tag{2.12}$$

$$-r_A = kC_A \tag{2.13}$$

$$-r_A = k{C_A}^n \tag{2.14}$$

The Monod Equation is a special case of the Michaelis-Menton kinetics and allows the rate equation to change from first to zero order if there is saturation of a substrate within a biological reaction (Equation 2.15). This saturation occurs because the bacteria reach their maximum metabolic rate and so the reaction rate is no longer dependent on concentration. The Monod Equation has been used as the basis for reaction rates in many models for CWs (Rajabzadeh, Legge and Weber, 2015; Deng *et al.*, 2016; Gargallo *et al.*, 2017; García *et al.*, 2020).

$$-r_A = V_{max} \frac{C_A}{k_m + C_A} \quad (2.15)$$

2.8.2 The CWM1

The International Water Association (IWA) CW Model No1 (CWM1) is a biokinetic model developed by Langergraber et al (2009) which describes the transformation and degradation processes of organic matter and nitrogen through microbial processes to predict the effluent concentrations of components in a sub-surface flow CW (Langergraber, Rousseau, *et al.*, 2009). Aerobic, anaerobic, and anoxic processes are modelled which allows CMW1 to be used for both HSSF and VF CWs. All microorganisms are considered particulate matter and referred to as bacteria only (Langergraber, Rousseau, *et al.*, 2009). The microorganisms are separated into bacterial groups, based on their function in treating wastewater. In the CWM1 model reaction rates are given for 17 biological processes and 16 contaminant groups are modelled. Particulate components are denoted X_i and soluble components are denoted S_i. A list of all components, their symbols and assumptions are included in Table 2.1. The components modelled in the CWM1 are organic matter, nitrogen species, sulfur species, and various bacterial groups. It is important to note that there is a difference between a reaction rate and the rate at which an individual component is degraded or consumed. Reaction rates refer to the rate at which one process involving multiple components takes place, while the rate at which a specific component is degraded or produced is based on the rate of the reactions in the component participates. In CWM1, the processes whose reaction rates are modelled include hydrolysis, growth of multiple bacterial groups, and lysis of these same groups. The reaction rates are given in a 17x1 matrix called the reaction rate matrix. Further details of these processes can be found in Table 2.2. The reaction rates given for growth of bacteria are based on Monod kinetics and, as a result, are not linear.

A second matrix of dimension 17x16, is included in the model and links the reaction rates with the rates at which the various components are produced and consumed according to each individual process. This is called the coefficient matrix. Each coefficient is denoted $\alpha_{li,}$ relating process 'l' and component 'i'. The table of coefficients can be found in Table 2.3. In most cases the components are involved in more than one reaction and these component rates become quite intricate, consisting of more than one term. Blank fields in the coefficient matrix indicate that the specific component, 'i' does not take place in process 'j' and therefore is not influenced

by the reaction rate of process ‘j’. The dot product of the coefficient matrix and the reaction rate matrix gives a matrix of component production or degradation rates, of dimensions 16x1.

Gaseous emissions are not predicted in this model and so methane was not considered a model component (Langergraber, Rousseau, *et al.*, 2009). CWM1 is merely a biokinetic model and therefore does not account for the hydraulics of a CW, the influence of planes, transport of suspended solids, or clogging. For a fully predictive model these processes must also be investigated.

***Table 2.1**: A list of all components modelled in the CWM1, their symbols, descriptions and units. Adapted from (Langergraber, Rousseau, et al., 2009)*

Component number	Type	Symbol	Description	Units	Soluble/ particulate
1	Dissolved Oxygen	S_O	Dissolved oxygen can be directly measured and is subject to gas exchange.	$M(O_2)\ L^{-3}$	Soluble
2	Fermentable, readily biodegradable COD	S_F	This fraction of the COD is directly available for biodegradation by heterotrophic and fermenting bacteria and is produced by hydrolysis.	$M(COD)\ L^{-3}$	Soluble
3	Fermentation products as acetate	S_A	All fermentation products are assumed to be acetate only. Removal of S_A occurs by aerobic and anoxic growth of heterotrophic bacteria and is produced from hydrolysis.	$M(COD)\ L^{-3}$	Soluble
4	Inert, soluble COD	S_I	S_I cannot be further degraded in the treatment plant and is assumed to be part of the influent organic matter and can be produced from hydrolysis	$M(COD)\ L^{-3}$	Soluble
5	Ammonium and ammonia nitrogen (NH_4^+-N and NH_3-N)	S_{NH}	S_{NH} is assumed to include all NH_4^+-N. As organic nitrogen is modelled as a fraction of the COD, S_{NH} is produced by degradation of organic matter. S_{NH} is degraded by nitrification and by incorporation during biomass growth.	$M(N)\ L^{-3}$	Soluble
6	Nitrate and Nitrite nitrogen (NO_3^--N and NO_2^-N)	S_{NO}	S_{NO} is assumed to include all nitrate and nitrite nitrogen since nitrite is not included as a separate model component. For stoichiometric equations S_{NO} is assumed to be NO_3^--N only. S_{NO} is produced from nitrification and consumed by denitrification and anoxic sulphide oxidation.	$M(N)\ L^{-3}$	Soluble
7	Sulphate sulphur	S_{SO4}	S_{SO4} is expressed as sulphur. Sulphate reducing bacteria uses S_{SO4} as an electron acceptor for oxidation of S_A. S_{SO4} is produced from aerobic and anoxic sulphide oxidation.	$M(S)\ L^{-3}$	Soluble
8	Dihydrogensulphide sulphur	S_{H2S}	S_{H2S} is produced by reduction of S_{SO4} whereas S_{H2S} is converted to S_{SO4} by sulphide oxidisers such as *Thiobacillus*	$M(S)\ L^{-3}$	Soluble
9	Slowly biodegradable particulate COD	X_S	X_S represents organic substances which have to undergo cell external hydrolysis before they are available for degradation. When bacteria die, the biodegradable parts of their cells are added to the amount of X_S. X_S loses occur through hydrolysis by heterotrophic bacteria.	$M(COD)\ L^{-3}$	Particulate
10	Inert particulate COD	X_I	This part of the particulate organic matter is not degraded in the system of interest. X_I is assumed to stay in the pore space unless higher flow rates exert enough shear stress to drag along solids.	$M(COD)\ L^{-3}$	Particulate
11	Heterotrophic bacteria	X_H	These organisms are assumed to be the 'allrounder' heterotrophic being responsible for hydrolysis, mineralization of organic matter (aerobic growth) and denitrification (anoxic growth).	$M(COD)\ L^{-3}$	Particulate
12	Autotrophic nitrifying bacteria	X_A	Nitrifying organisms are responsible for nitrification. It is assumed that S_{NH} is nitrified to S_N. Nitrite, as an intermediate product of nitrification, is not considered.	$M(COD)\ L^{-3}$	Particulate
13	Fermenting bacteria	X_{FB}	Under anaerobic conditions fermenting bacteria consume fermentable, readily biodegradable COD (S_F) and produce acetate (S_A).	$M(COD)\ L^{-3}$	Particulate
14	Acetotrophic methanogenic bacteria	X_{AMB}	Anaerobically growing acetotrophic methanogenic bacteria consume acetate (S_A) and produce methane (which is not considered as a model component).	$M(COD)\ L^{-3}$	Particulate
15	Acetotrophic sulphate reducing bacteria	X_{ASRB}	Sulphate reducing bacteria use S_{SO4} as an electron acceptor for oxidation of acetate (S_A) and produce S_{H2S}.	$M(COD)\ L^{-3}$	Particulate
16	Sulphide oxidising bacteria	X_{SOB}	Sulphur oxidising bacteria are chemautotrophic organisms that use oxygen S_O or nitrate S_{NO} to oxidise sulphide (S_{H2S}) to sulphate (S_{SO4}).	$M(COD)\ L^{-3}$	Particulate

***Table 2.2**: A list of all the process modelled in the CWM1 and the rates at which they proceed. Adapted from (Langergraber, Rousseau, et al., 2009)*

Process number	Process	Process rate ρ_j
1	Hydrolysis	$k_h * \left[\frac{\frac{X_s}{X_H + X_{FB}}}{K_X + \frac{X_s}{X_H + X_{FB}}}\right] * (X_H + \eta_h * X_{FB})$
2	Aerobic growth of heterotrophic bacteria on fermentable, readily biodegradable COD	$\mu_H * \left[\frac{S_F}{K_{SF} + S_F}\right] * \left[\frac{S_F}{S_F + S_A}\right] * \left[\frac{S_O}{K_{OH} + S_O}\right] * \left[\frac{S_{NH}}{K_{NHH} + S_{NH}}\right] * \left[\frac{K_{H2SH}}{K_{H2SH} + S_{H2S^*}}\right] * X_H$
3	Aerobic growth of heterotrophic bacteria on fermentation products as acetate	$n_g * \mu_H * \left[\frac{S_F}{K_{SF} + S_F}\right] * \left[\frac{S_F}{S_F + S_A}\right] * \left[\frac{K_{OH}}{K_{OH} + S_O}\right] * \left[\frac{S_{NO}}{K_{NOH} + S_{NO}}\right] * \left[\frac{S_{NH}}{K_{NHH} + S_{NH}}\right] * \left[\frac{K_{H2SH}}{K_{H2SH} + S_{H2S^*}}\right] * X_H$
4	Anoxic growth of heterotrophic bacteria on fermentable, readily biodegradable COD	$\mu_H * \left[\frac{S_A}{K_{SA} + S_A}\right] * \left[\frac{S_A}{S_F + S_A}\right] * \left[\frac{S_O}{K_{OH} + S_O}\right] * \left[\frac{S_{NH}}{K_{NHH} + S_{NH}}\right] * \left[\frac{K_{H2SH}}{K_{H2SH} + S_{H2S^*}}\right] * X_H$
5	Anoxic growth of heterotrophic bacteria on fermentation products as acetate	$n_g * \mu_H * \left[\frac{S_A}{K_{SA} + S_A}\right] * \left[\frac{S_A}{S_F + S_A}\right] * \left[\frac{K_{OH}}{K_{OH} + S_O}\right] * \left[\frac{S_{NO}}{K_{NOH} + S_{NO}}\right] * \left[\frac{S_{NH}}{K_{NHH} + S_{NH}}\right] * \left[\frac{K_{H2SH}}{K_{H2SH} + S_{H2S^*}}\right] * X_H$
6	Lysis if heterotrophic bacteria	$b_H * X_H$
7	Growth of autotrophic nitrifying bacteria on ammonium and ammonia nitrogen	$\mu_A * \left[\frac{S_{NH}}{K_{NHA} + S_{NH}}\right] * \left[\frac{S_O}{K_{OA} + S_O}\right] * \left[\frac{K_{H2SA}}{K_{H2SA} + S_{H2S^*}}\right] * X_A$
8	Lysis of autotrophic nitrifying bacteria	$b_A * X_A$
9	Growth of fermenting bacteria	$\mu_{FB} * \left[\frac{S_F}{K_{SFB} + S_F}\right] * \left[\frac{K_{H2SFB}}{K_{H2SFB} + S_{H2S^*}}\right] * \left[\frac{K_{OFB}}{K_{OFB} + S_O}\right] * \left[\frac{K_{NOFB}}{K_{NOFB} + S_{NO}}\right] * \left[\frac{S_{NH}}{K_{NHFB} + S_{NH}}\right] * X_{FB}$
10	Lysis of fermenting bacteria	cc
11	Growth of acetotrophic, methanogenic bacteria	$\mu_{AMB} * \left[\frac{S_A}{K_{SAMB} + S_A}\right] * \left[\frac{K_{H2SAMB}}{K_{H2SAMB} + S_{H2S^*}}\right] * \left[\frac{K_{OAMB}}{K_{OAMB} + S_O}\right] * \left[\frac{K_{NOAMB}}{K_{NOAMB} + S_{NO}}\right] * \left[\frac{S_{NH}}{K_{NHAMB} + S_{NH}}\right] * X_{AMB}$
12	Lysis of acetotrophic, methanogenic bacteria	$b_{AMB} * X_{AMB}$
13	Growth of acetotrophic sulphate reducing bacteria.	$\mu_{ASRB} * \left[\frac{S_A}{K_{SASRB} + S_A}\right] * \left[\frac{S_{SO4}}{K_{SOASRB} + S_{SO4}}\right] * \left[\frac{K_{H2SASRB}}{K_{H2SASRB} + S_{H2S^*}}\right] * \left[\frac{K_{OASRB}}{K_{OASRB} + S_O}\right] * \left[\frac{K_{NOASRB}}{K_{NOASRB} + S_{NO}}\right] * \left[\frac{S_{NH}}{K_{NHASRB} + S_{NH}}\right] * X_{ASRB}$
14	Lysis of acetotrophic sulphate reducing bacteria.	$b_{ASRB} * X_{ASRB}$
15	Aerobic growth of sulphide oxidising bacteria on dihydrogen sulphide	$\mu_{SOB} * \left[\frac{S_{H2S}}{K_{SSOB} + S_{H2S}}\right] * \left[\frac{S_O}{K_{OSOB} + S_O}\right] * \left[\frac{S_{NH}}{K_{NHSOB} + S_{NH}}\right] * X_{SOB}$
16	Anoxic growth of sulphide oxidising bacteria on dihydrogen sulphide	$\mu_{SOB} * \eta_{SOB} * \left[\frac{S_{H2S}}{K_{SSOB} + S_{H2S}}\right] * \left[\frac{S_{NO}}{K_{NOSOB} + S_{NO}}\right] * \left[\frac{K_{OSOB}}{K_{OSOB} + S_O}\right] * \left[\frac{S_{NH}}{K_{NHSOB} + S_{NH}}\right] * X_{SOB}$

2.8.3 The CW2D

CW2D is another multi-component model, with a very similar basis to CWM1. This biokinetic model includes the production and degradation of 12 components including dissolved oxygen, organic matter (three fractions of different degradability), ammonium, nitrite, nitrate, and dinitrogen-nitrogen, inorganic phosphorus, and heterotrophic and autotrophic micro-organisms. There are 9 processes considered which include hydrolysis, mineralization of organic matter, nitrification (which is modelled as a two-step process), denitrification, and a lysis process for the micro- organisms. CW2D is set up in the same way as CWM1 with two matrices which give the process reaction rates and stochiometric coefficients connecting the components to the processes.

Like CWM1, CW2D is a biokinetic model and does not factor in the hydraulic flow behaviour of a CW. For this reason, CW2D is used in conjunction with other models. CW2D has been integrated into two comprehensive models, HYDRUS and BIO_PORE, both of which are discussed in more detail in Section 2.9.

2.9 Hydraulic Modelling of Constructed Wetlands

CWs are essentially reactors and one of the factors which affects the extent of reaction is the time the fluid spends in the CW. Investigation into the hydraulic behaviour of a CW allows for the determination of this time and subsequently the effectiveness of the system in reducing contaminant load. Therefore, for CW models to be accurate the characterisation of hydraulic behaviour must be accurate. The flow behaviour of a wetland influences its ability to break down inlet contaminants (Kadlec and Wallace, 2009). There is a distribution of flow velocities within the system and the combination of these gives the overall hydraulic behaviour of the system. The water moving at the maximum velocity in the profile would normally be in the surface layer of the micro-channels, while the lowest velocity is experienced by water that moves near drag-inducing surfaces, such as the wetland bottom (Werner and Kadlec, 2000). Investigations have found that there are 3 different hydraulic zones in CWs; the main flow path, a temporary storage zone, where components and water are exchanged with the main flow path, and a dead zone (Buchberger and Shaw, 1995; Zahraeifard and Deng, 2011). By investigating the hydraulic behaviour of a CW, it is possible to give an indication of whether there are hinderances to ideal flow such bypassing, dispersion, and dead zones. All these factors contribute to the time that wastewater spends in the wetland, known as the residence time. This

in turn relates to how long the water is in the system to break down organics, convert nitrogen species, and degrade other contaminants. If a wetland has poor hydraulic behaviour, then pollutant removal will be poor and conversion for which the system was designed, will not be achieved.

2.9.1 Ideal Reactor Equations

For design purposes, it can be tempting to model CWs using ideal flow behaviour, either as a plug flow reactor (PFR) or as a continuously stirred tank reactor (CSTR). In an ideal PFR every fluid particle moves through the reactor with the same velocity and have the same residence time. There is assumed to be no dispersion or longitudinal mixing. The design equation for a first-order reaction in a PFR is given in Equation 2.16. In an ideal CSTR it is assumed that the system is perfectly mixed which implies that the effluent concentration is the same as the concentration anywhere in the reactor. Equation 2.17 gives the design equation for a first order reaction in an ideal CSTR. However, it has been shown by multiple researchers that the hydraulic behaviour of CWs is far from these ideal cases, and likely lies somewhere in between (Kadlec, 2000; Werner and Kadlec, 2000).

$$C_{i,out} = C_{i,in} e^{-kt} \tag{2.16}$$

$$C_{i,out} = \frac{C_{i,in}}{(1+kt)} \tag{2.17}$$

The reason an ideal PFR equation is often chosen is that the solution to the kinetics is the same as a batch reactor, with time ‘t’ being the same as ‘tau’. While this makes the equation easy to use, it is not necessarily accurate. If the hydraulic behaviour of CWs is to be modelled accurately, non-ideal flow must be considered.

2.9.2 Reasons for Non-ideal Flow

The flow characteristics of CWs are elaborate and non-ideal owing to the changing root structure and the complicated flow pathway of fluid through gravel or soil matrix (Bonner et al., 2017). Factors such as wetland shape (Persson, 2000; Wörman and Kronnäs, 2005), inlet and outlet location (Persson, Somes and Wong, 1999; Suliman, Futsaether, *et al.*, 2006), and vegetation distribution (Persson, Somes and Wong, 1999; Serra, Fernando and Rodríguez, 2004; Kjellin *et al.*, 2007; Keefe *et al.*, 2010) can affect the hydraulic behaviour of CWs. These factors result in non-ideal phenomena like dispersion, short-circuiting, and dead zones.

Dispersion

Dispersion in an effect of the micro-mixing of the fluid in the direction of the flow. This leads to a 'spreading' of the pocket of fluid. This phenomenon occurs because the flow channels are non-ideal and have different lengths and are oriented in different directions.

Short circuiting

Short circuiting occurs when some of the fluid bypasses the main flow channel and follows the path of least resistance, resulting in this pocket of fluid passing through the system in a much shorter period of time than the rest of the fluid.

Dead zones

Dead zones are areas of very low or no flow within a system. In these stagnant pockets the dominant process for solute transport is diffusion. The presence of dead zones decreases the effective volume of the overall system and therefore reduces the system's ability to treat wastewater.

Wetland clogging

Wetland clogging is considered to be one of the biggest operational problems of CWs. This phenomenon is typically caused by the following processes (Kadlec, 2009).

- Deposition of suspended solids at the system inlet;
- Deposition of organic compounds, which are resistant to microbial degradation, at the system inlet;
- Chemical precipitation;
- Introduction of organic matter to the system which encourages growth of microbial biofilms in the plant rhizosphere;
- Growth of plant roots within the packed media; and
- Gas bubble dynamics.

Heterogenous sub-surface media

Gravel and soil are among the most commonly used CW media. These materials are typically heterogeneous in nature and are found to have particle size distributions (Suliman, French, *et al.*, 2006). This variation in particle sizes results in a variation in pore sizes throughout the

wetland that can lead to the development of preferential flows paths. The presence of vegetation also increases the heterogenous nature of the system. Vegetation distribution is a variable barrier to flow in terms of the plant size, shape, and position. As a result, there is bypass and short circuiting around plant mass, forming dead zones, which leads to a hold up of water in certain areas.

2.9.3 Tracer Tests

The most common way to characterise the flow patterns and assess the hydraulic behaviour of a CW is by conducting residence time distribution (RTD) studies or tracer studies (Headley and Kadlec, 2007). The residence time distribution of a reactor gives the probability of a fluid element spending a specific amount of time in the reactor and is characteristic of the mixing that occurs within the system (Fogler, 2006). The RTD is obtained by running a flow tracer study on the system. A flow tracer study is a stimulus-response experiment in which an inert flow tracer is injected either as an impulse or as a step-change in concentration into the system inlet pipe and the tracer concentration is measured continuously at the effluent. An effective tracer study requires the flow to be laminar (Sheridan, Hildebrandt and Glasser, 2013) if the data is to be successfully extrapolated (scaled) to other operational flow rates (as long as they are also laminar). Data from these experiments are then used in RTD modelling methodologies to analyse the flow characteristics of the reactor and can be used to quantify a set of characteristics that describe the hydraulic behaviour of CWs (Bonner *et al.*, 2017). In order for these tracer tests to be effective the tracer used must be conservative, i.e. should not be consumed or degraded (Cucco and Umgiesser, 2006). The tracer should also not be susceptible to biological, chemical, or photochemical decay, should be highly soluble in water, and should be easily detectable and not exist at high background levels within the system. It is also assumed that for any experiment run, the tracer flow behaviour is similar to a normal effluent liquid (Lappalainen *et al.*, 2011).

Impulse-Response tracer tests

The type of tracer study most commonly used to determine the hydrodynamic behaviour of a CW is the impulse-response test (Headley and Kadlec, 2007; Kadlec, 2007). When conducting an impulse-response test a small volume of highly concentrated tracer solution is injected instantaneously (mathematically equivalent to an impulse function) into the inlet of the system and the concentration of the tracer is measured at the effluent at regular time intervals (Fogler,

2006). In Figure 2.8 a graphical representation of the concentration-time response at the inlet (a) and outlet (b) can be seen. The very short impulse is observed to spread (or disperse) through any system. If the results follow a normal (Gaussian) distribution, the flow is normally ideal. The shape of the distribution can tell the experimenter many things: if it is bi- or multi-modal (two or more peaks) it can indicate bypass , if it has a very long tail, it can indicate dead-zones as the tracer 'bleeds' back from the dead-zone into the outlet.

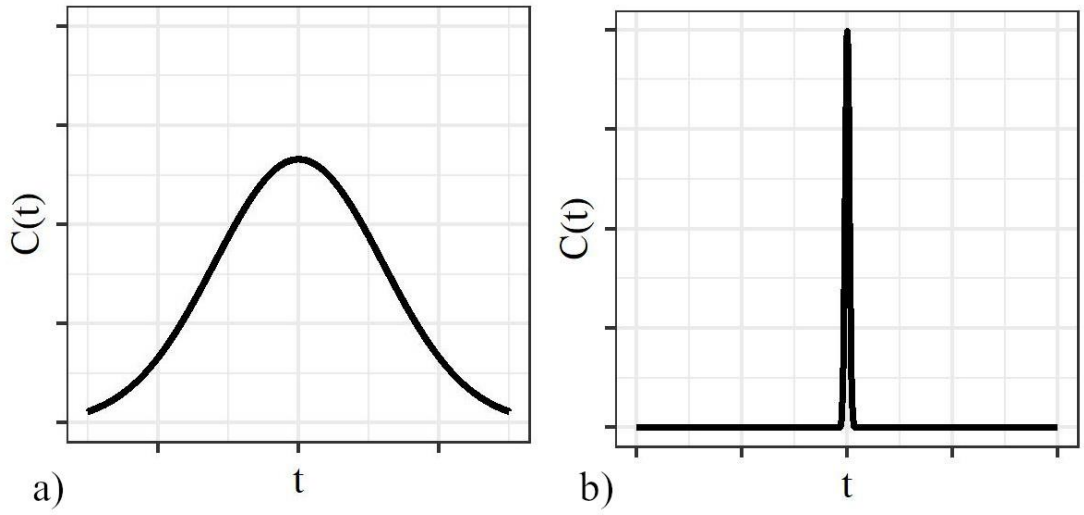

Figure 2.8: *A graphical representation of the concentration-time response of an impulse-response tracer test: inlet (a) and outlet (b).*

The residence time distribution function, E(t), which is a quantitative description of how much time the fluid particles have spent in the reactor, can be obtained from concentration-time data of the impulse-response curve, and is given by Equation 2.18. The basis assumption for Equation 2.18 is that the inlet volumetric flow rate of the system is constant. E(t) is calculated using the area under the concentration-time curve; by doing so the area underneath the E(t) vs t response curve is 1. The calculation of E(t) is important as the first step towards calculating the moments of the distribution (i.e., the first moment is the mean of the RTD, the second moment is the spread of the distribution – these are discussed further later).

$$E(t) = \frac{C(t)}{\int_0^\infty C(t)dt} \tag{2.18}$$

Two of the problems associated with an impulse-response tracer study are ensuring that the injection of tracer takes places over a period of time which is short compared to the residence time of the system, and ensuring negligible dispersion of the tracer between the point of injection and the feed to the system. Another issue than can arise is that if the experiment has

been concluded too early, then the analysis of the concentration-time data from the effluent can lead to inaccuracies. It is important is extrapolate the tail of the impulse-response to prevent this. A further major obstacle with the impulse-response tracer test is that there may be the same concentration at various times (i.e., on the way towards the peak(s) and on the way down from the peak(s)). This means that the actual time a molecule has spent in the reactor is not known, and rather there are probabilities of time that reactants spend in the reactor.

Step change tracer tests

The other primary type of tracer study is a step-change response test. For this experiment a constant rate of tracer is fed into the system starting at $t = 0$. The concentration of this tracer must be significantly higher than the background concentration and easy to quantify analytically. The effluent concentration is monitored at regular time intervals (Vonortas *et al.*, 2011) until the outlet concentration is stable and equal to that of the inlet (this will only happen if the tracer is conservative – if not, the outlet will reach a steady-state value). A graphical representation of the concentration-time behaviour of the typical inlet and outlet response of step-change tracer tests is shown in Figure 2.9.

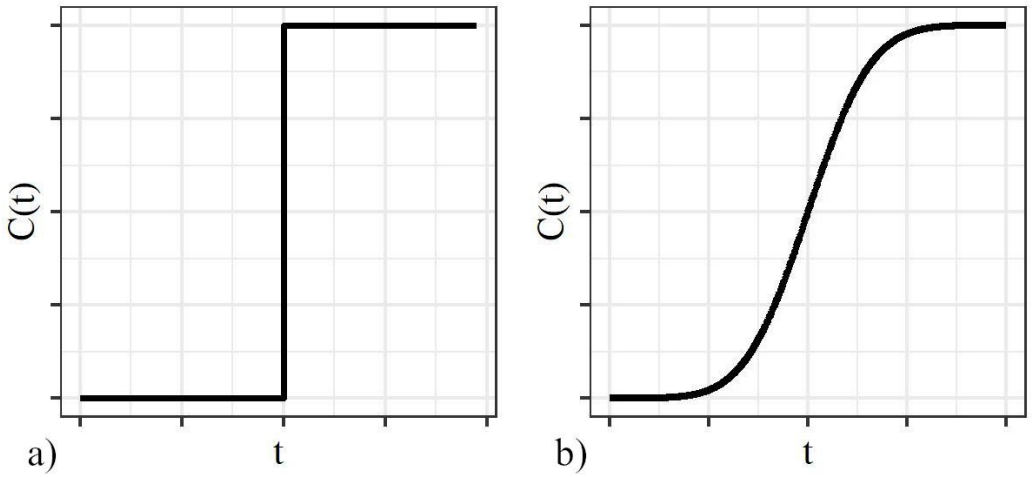

Figure 2.9*: A graphical representation of the concentration-time response of a step-change response tracer test: inlet (a) and outlet (b).*

From the concentration-time data of the step-change response experiment, the cumulative distribution, F(t), can be obtained. F(t) is described as the fraction of effluent that has been in the system for less than time t. The mathematical definition of the cumulation distribution is given in Equation 2.19 (Fogler, 2006). F(t) can also be considered the normalised response to the step input.

$$F(t) = \left[\frac{C_{out}}{C_{inlet}}\right]_{step} \tag{2.19}$$

Some of the challenges associated with step-change response tracer studies include difficulty maintaining a constant feed concentration, a large amount of tracer is required, and the analysis of step-change response data involves differential mathematics rather than integral mathematics. This can result in large errors and a serious increase in noise in the data (Fogler, 2006). One of the benefits of this study is that it is not necessary to know the total amount of tracer added to the system.

The relationship between the residence time distribution function (E(t)) and the cumulative distribution function, is given in Equation 2.20. This integral relationship allows for the conversion from impulse-response data to step change response data, if desired. Because of this relationship it is possible to determine the hydraulic parameters from the cumulative distribution function from the residence time distribution function.

$$\int_0^t E(t)dt = F(t) \tag{2.20}$$

Square input tracer tests

Square input tracer tests are uncommon and not covered in common literature. In this form of tracer study, the feed concentration is increased from 0 to a significantly higher and measurable concentration at t=0 and then at t=t* the feed concentration is stepped back down to 0. Giraldi et al., (2009) used square input tracer tests when conducting tracer tests on VF CWs to determine the hydrodynamics in different saturation conditions (Giraldi *et al.*, 2009). The square input signal was artificially extended to take the form of a step change input signal using Equation 2.21, where C(t) is the normalized tracer concentration and t* is the time where the dosing of tracer for the square input was stopped. In other words, it is essentially a double step-change – one up, and one down.

$$\begin{cases} F(t) = C(t) & , t \leq t^* \\ F(t) = C(t) + F(t - t^*) & , t > t^* \end{cases} \tag{2.21}$$

The response curve of the different types of experiments can be used to quantify the hydraulic behaviour of the system using the method-of-moments analysis as well as other reactor models such as the tanks-in-series model and the advective-dispersive transport models (Langergraber, Giraldi, *et al.*, 2009).

Types of tracers

There are many options of tracers available which include, but are not limited to: salt ions, fluorescent dyes, and stable isotopes, or a combination of these of tracers. All of these options have been used by researchers conducting tracer tests in CWs.

Salt tracers

Salt tracers, also known as ionic tracers, are considered to be effective for studying the hydraulic behaviour of CWs as they are easily soluble and are unlikely to interact with the biota of the system (Lin *et al.*, 2003). Sodium chloride is one of the most common salt tracers and has been used by many researchers. Heiderscheidt et al. (2020) used it to determine the residence time under frozen and frost-free conditions of an unplanted, peat-based, pilot-scale wetland (Heiderscheidt *et al.*, 2020), Sun et al. (2019) used it to determine hydraulic parameters of a horizontal sub-surface flow CW (Sun *et al.*, 2019) and Hua et al. made use of the tracer to investigate the effect of clogging and resting processes on the flow behaviour of a vertical flow CW (Hua *et al.*, 2018). One study used lithium as a tracer to validate the hydraulic model used in a CWM1-RETRASO mechanistic model in the simulation of a horizontal sub-surface flow CW (Mburu *et al.*, 2013), while another used lithium chloride to test the effect of inlet configuration and vegetation type on the hydraulic performance of 18 free water surface wetlands (Bodin *et al.*, 2012). Potassium iodide was used by a group of researchers to determine the hydraulic behaviour of drained peatlands (Postila *et al.*, 2015).

One of the limitations of salt tracers is that the salt solutions typically have higher densities than the wetland water (Bodin *et al.*, 2012) and so a halocline could be formed. This results in the stratification of fluid which prevents mixing and is thermodynamically stable. Density induced stratification may be aided by low flow velocities (Schmid, Hengl and Stephan, 2004). Special care needs to be taken, especially in the case of impulse-response tracer tests, to ensure that salt tracer settling does not take place. Density differences are also affected by temperature, but in FWS wetlands the temperature difference from top to bottom is approximately 1°C which is not considered enough to create stratification (Kadlec and Wallace, 2009). Any temperature differences greater than this may cause a problem (Bodin *et al.*, 2012).

When choosing a salt tracer, choosing one with ions that have minimal interaction with the system is important. For example, Cl^- and Li^+ are good ionic tracers but NO_3^- will be transformed in the system and therefore is not a conservative tracer. It is also important to

consider the charge of the ion and the charge of the wetland medium, to ensure minimal interaction between the two.

Chemical analytical methods most commonly used for salt tracers are electrical conductivity and ion chromatography and, in some cases, atomic absorption spectrophotometry. Electrical conductivity is a cheap and effective method of analysis and can be used as a proxy for determining the concentration of ions in the system.

Fluorescent tracers

The use of fluorescent tracers in the RTD studies of CWs is common. Fluorescent dyes such as fluorescein and rhodamine are inexpensive, easy to handle and easy to detect (Russell *et al.*, 1992). One study used rhodamine WT to evaluate hydraulic behaviour and performance indicators of various wetlands designs and from this information were able to choose the optimum design from the systems tested on (Guo *et al.*, 2019). Guo et al. (2019) used rhodamine WT to determine the residence time and other hydraulic parameters of a tundra wetland and from this were able to determine first-order rate constants of the contaminants which can be used to further improve the wetland design (Hayward and Jamieson, 2015). Another common fluorescent dye tracer is uranine. Pálfy et al. (2017) used uranine to determine the hydraulic behaviour of a wetland treating combined sewer overflow and from this information the researchers were able to identify short circuiting as a limitation of the system (Pálfy *et al.*, 2017), while Laurent et al. (2015) used uranine and sulfurhodamine B to successfully determine the hydrodynamic behaviour of three surface flow CWs (Laurent *et al.*, 2015)**.** These dyes are for the most part conservative but have the potential to adsorb onto certain materials, are susceptible to photodegradation and biodegradation, and can be pH sensitive (Lin *et al.*, 2003; Gerke, Sidle and Mallants, 2013).

Combinations of different types of tracers

A combination of two or more types of tracers is being trialled by wetland researchers for RTD studies. Different tracers have different diffusion coefficients, and this allows researchers to determine the presence and location of stagnant zones and diffusion dominated transport processes (Knorr *et al.*, 2016). Birkigt et al. (2018) conducted a multi-tracer RTD experiment using bromide, uranine and deuterium oxide to determine the flow behaviour in three dimensions of a pilot-scale HSSF CW (Birkigt *et al.*, 2018). From this research it was noted that bromide and deuterium oxide had similar behaviour and the data from the tracer studies yielded similar hydraulic parameters while uranine displayed a different hydraulic behaviour. It was suggested that there was a lag in the response of uranine due to organic matter in the system. Mailard et al. (2016) used bromide, uranine and sulforhodamine-B as tracers to determine the impact of batch versus continuous-flow modes on the dissipation of the chiral herbicide S-metolachlor in a CW (Maillard *et al.*, 2016). These researchers found that plant uptake, sorption, and photodegradation is greater in batch mode operation than continuous flow operation, but the extent for each tracer was slightly different. Bromide was most susceptible to plant uptake, uranine was most susceptible to photodegradation and sulforhodamine-B was most susceptible to sorption (Maillard *et al.*, 2016). Pugliese et al. (2020) used uranine and potassium bromide as conservative tracers to study the hydraulic behaviour of a shallow-deep, compartment-designed sub-surface flow CW and were able to identify the presence of multiple flow paths and internal mixing in shallow zones (Pugliese *et al.*, 2020). Montalván et al. (2017) used natural tracers (Cl^-, Br^-, Na^+, Mg^{2+}) and environmental isotopes (^{18}O, ^{2}H, ^{14}C, ^{13}C and ^{3}H) to estimate residence times of brine waters and identify recharge areas of the different flow subsystems in a hypersaline wetland (Montalván *et al.*, 2017). Bruun et al. used bromide and tritium (in the form of $^{3}H_2O$) to investigate intra-granular diffusion in a woodchip based sub-surface flow CW (Bruun *et al.*, 2016). This study indicated that there may be a slight anion exclusion on bromine in the wood chip matrix.

Other tracer options

While the tracer types mentioned above are the more common, a few others have been used. Bonner et al. (2017) developed a mapping methodology for the use of heat as a non-conservative tracer in HSSF CWs. The researchers were able to accurately quantify the hydraulic parameters of the system being tested on from the mapped heat tracer response. It was shown that if certain parameters of transport can be determined then this technique can be

used. One study used stable isotope ratios of oxygen ($\delta^{18}O$) and hydrogen ($\delta^{2}H$) in water to study the hydrology of forested wetlands (Bugna, Grace and Hsieh, 2020). Through this, the researchers were able to identify the contribution of surface water and rainwater to three different wetland systems and the extent of surface evaporation. Abu-Bakar et al. (2017) investigated the use of microbial tracers and in this study the researchers calibrated and validated the transport and decay of four microbial tracers and used the data to refine a model for better water quality processes in a macro-tidal coastal basin. Modelling the decay of the microbial tracers proved to be more computationally intensive than the researchers expected so the technique is not considered useful for design (Abu-Bakar, Ahmadian and Falconer, 2017).

2.9.4 Hydraulic Modelling Techniques

In an ideal plug-flow system, all fluid particles move through the wetland with the same velocity and reach the system outlet at the same time. This exit time is the simplest way to account for time in a CW and is called the nominal residence time (τ) which is defined in Equation 2.22 (Headley and Kadlec, 2007). The nominal residence time is only a function of velocity ($\dot{v}$) and volume (V) and is an intrinsic parameter of any reactor. This method does not account for any non-ideal flow through the wetland system and a tracer test is not required to determine the nominal residence time. Owing to the non-ideal nature of wetland hydraulic behaviour, the nominal residence time is not considered sufficient to characterise wetland flow behaviour.

$$\tau = \frac{V}{\dot{v}} \tag{2.22}$$

Method-of-moments

In the method-of-moments technique for interpreting RTD data, three parameters are determined: the mass recovery, the mean residence time, and the variance. The mass recovery of tracer in an RTD study is important, especially in an impulse-response study, as many parameters used to quantify the hydraulic behaviour of a system are determined based on the assumption of total mass recovery. A mass recovery of tracer of 80% or higher is generally considered acceptable (Headley and Kadlec, 2007). The percentage of mass recovery of conservative tracer in a tracer study is considered the zeroth moment of the RTD. The mass recovery can be calculated using Equation 2.23 (Holland *et al.*, 2004).

$$M_{out} = \int_0^\infty Q_{out}(t)C_{out}(t)dt \quad (2.23)$$

The first moment of the RTD study is the centroid of the response curve, and is called the mean residence time (t_m), which is the average amount of time that the fluid particles have spent in the reactor. This can be calculated using Equation 2.24 (Fogler, 2006) for impulse-response tracer studies and Equation 2.25 (Bonner *et al.*, 2017) for step-change response tracer studies.

The second moment of the RTD is the variance. The variance is an indication of the spread of the impulse as it passes through the reactor system (Drummond *et al.*, 2012; Jackson *et al.*, 2012). Equation 2.26 (Luo *et al.*, 2008) and Equation 2.27 (Bonner *et al.*, 2017) give the equation used to determine the variance from an impulse-response and step change tracer study, respectively. The variance gives an indication of the global mixing in the system (Giraldi *et al.*, 2009).

$$t_m = \frac{\int_0^\infty tE(t)dt}{\int_0^\infty E(t)dt} \quad (2.24)$$

$$t_m = \int_0^\infty [1 - F(t)]dt \quad (2.25)$$

$$\sigma^2 = \int_0^\infty (t - t_m)^2 E(t)dt \quad (2.26)$$

$$\sigma^2 = 2\int_0^\infty t[1 - F(t)]dt - {t_m}^2 \quad (2.27)$$

Dimensionless variance is calculated using Equation 2.28. The dimensionless variance gives an indication of local mixing.

$${\sigma^2}_0 = \frac{\sigma^2}{{t_m}^2} \quad (2.28)$$

The mean residence time (t_m) can be compared to the nominal residence time (τ) to provide the effective volume utilisation (*e*). This is given in Equation 2.29 (Bodin *et al.*, 2012). The effective volume utilisation is a function of aspect ratio (Molle, Prost-Boucle and Lienard, 2008), positioning of inlet and outlet ports (Sheridan *et al.*, 2013), presence and location of plants in the system, and root density (Pedescoll *et al.*, 2013) as well as the extent of clogging in the system due to biofilm growth (Knowles *et al.*, 2011). Evapotranspiration can influence the mean residence time and effective volume utilisation. If a large fraction of water is lost

from the system due to evapotranspiration it has a concentrating effect on the tracer. This affects the outlet concentrations of tracer obtained during tracer studies which in turn affects the mean residence time and other hydraulic parameters.

$$e = \frac{t_m}{\tau} \tag{2.29}$$

One of the limitations of the method-of-moments is that the anomalies in the tail of the impulse-response tracer test can lead to incorrect estimation of parameters and curve fitting (Kadlec and Wallace, 2009). Early truncation of the tail can also lead to an under estimation of the mean residence time (Martin, 2000). It has been indicated that a disadvantage of using the method-of-moments technique is that a single mean residence time (t_m) can describe an infinite number of distributions, thereby stating that there is a 'loss of information' when determining other parameters, such as dispersion, from the mean residence time (Bachmann and Tsotsas, 2015). The methods of moments is also sensitive to non-continuous data sets (Bodin *et al.*, 2012). The benefit of the method-of-moments technique is that the hydraulic parameters values can be obtained directly from the measured data (Bodin *et al.*, 2012).

The Peclet number (Pe) represents the ratio between the advective and dispersive contributions to solute transport within the system and is defined according to Equation 2.30.

$$Pe = \frac{uL}{D} \tag{2.30}$$

Tanks in Series Model

The tanks-in-series model is a reactor model and is a gamma distribution of residence times. The model is given in Equation 2.31 (Kadlec and Wallace, 2009). In this model the results from the tracer test, either step-change or impulse-response, are analysed to determine how many continuously stirred equally sized tank reactors in series would provide the same response curve as the experimental wetland curve. The number of tanks in series, N, is determined using Equation 2.32 (Bodin *et al.*, 2013). When N=1 there is a large degree of back mixing and the wetland is considered to behave as a CSTR and can be modelled as such. As N tends to infinity the degree of back mixing tends to zero and the behaviour of the wetland tends to that of an ideal plug flow reactor (PFR) and can be modelled as such. In Figure 2.10 the residence time distribution's varying values of N can be found. A physical representation of 6 tanks in series

is given in Figure 2.11. Based on reported literature values, Kadlec & Wallace (2009) estimated that N = 4.1 ± 0.4 for free water surface (FWS) wetlands, and N = 11.0 ± 1.2 for horizontal sub-surface flow wetlands (Kadlec and Wallace, 2009).

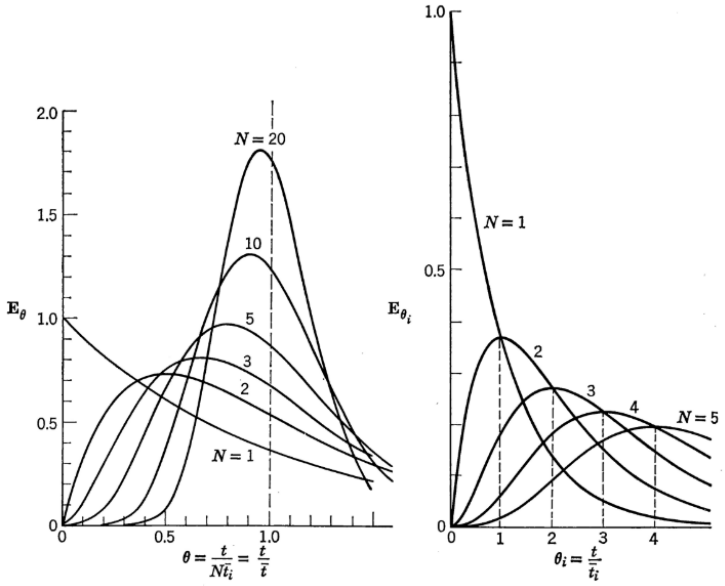

Figure 2.10: *residence time distributions varying values of N (Levenspiel, 1999)(Levenspiel, 1999)*

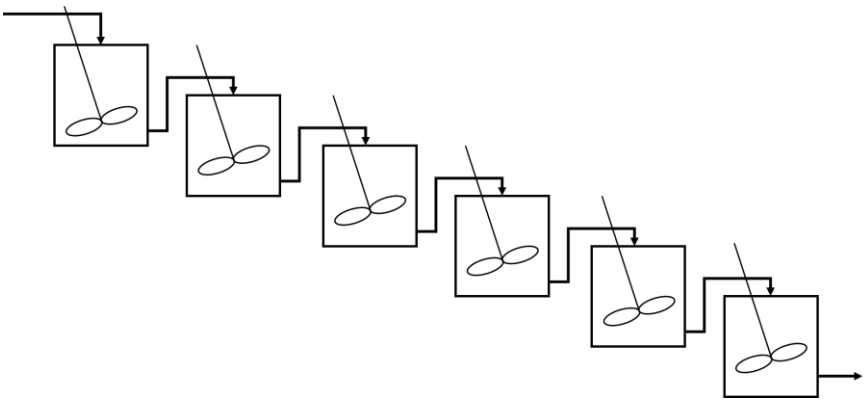

Figure 2.11*: Physical representation of multiple tanks in series where N=6*

$$E(t) = \frac{t^{N-1}}{(N-1)!{\tau_i}^n} e^{-\frac{t}{\tau_i}} \tag{2.31}$$

$$N = \frac{{t_m}^2}{\sigma^2} \tag{2.32}$$

From the number of tanks in series another factor can be determined, the hydraulic efficiency, which is defined in Equation 2.33. Hydraulic efficiency is a measure that can be used to

compare different wetland designs (Persson and Wittgren, 2003). It considers the effective volume utilisation (*e*) as well as the degree of mixing by making use of N.

$$\lambda = e * \left(1 - \frac{1}{N}\right) \tag{2.33}$$

One study used the tanks-in-series model to investigate the hydraulic behaviour of three large-scale surface flow CWs and it was determined that the vegetation density had a large effect on the dispersion of the system (Laurent *et al.*, 2015). Another study used the tanks-in-series model with exchange between active and dead zones to simulate the RTD of a horizontal sub-surface flow CW (Goswami *et al.*, 2019). From this model the researchers were able to determine the optimum inlet flow rate and water level in the CW being studied.

Advective-dispersive transport with retardation and decay

The advective-dispersive transport model with retardation and decay quantifies the transport of a single soluble species which undergoes both decay and retardation. This model is based on the assumptions that the porous media through which fluid flows is homogenous, isotropic and saturated, and that the fluid flow is steady-state and Darcy's Law applies (Wynn and Liehr, 2001). Darcy's Law describes the linear relationship between fluid flow rate and pressure gradient and applies in cases where the flow is laminar, and the porous medium has a large enough surface area exposed to fluid flow. The advective-dispersive transport equation can be used to describe the movement of a chemical tracer in sub-surface media and the one-dimensional form is given in Equation 2.34. This equation describes the transport of a single solute along the length of the reactor and can be applied to horizontal sub-surface flow CWs but cannot be applied to other wetland types. μ and γ are the first-order decay coefficient and zero-order production term, respectively, and can be used for non-conservative reactive chemical tracers (Malaguerra, Albrechtsen and Binning, 2013). R, a chemical retardation factor, is included in the transport equation and is provided in Equation 2.35. This retardation factor includes a distribution coefficient, K_d, which gives an indication of the solute concentration in the solid and the liquid (Morrison, 2015a). A K_d value close to 0 is considered non-sorbing and an increase in the K_d value indicates a larger sorbing tendency. The value depends on the physical characteristics of the tracer and, in some cases, the sub-surface media. D is the hydrodynamic dispersion coefficient and is a measure of describing the mixing of solutes in porous media (Shi *et al.*, 2016).

$$R\frac{\partial C}{\partial t} = D\frac{\partial^2 C}{\partial x^2} - u\frac{\partial C}{\partial x} - \mu C + \gamma \tag{2.34}$$

$$R = 1 + \frac{\rho_b K_d}{\varepsilon} \tag{2.35}$$

Retardation (R), hydrodynamic dispersion (D), and first-order decay (μ) have an effect on the residence time distribution response curve. For materials that are non-sorbing R is equal to 1. This indicates that the transport of the solute is the same as that of the water (Boy-Roura *et al.*, 2018). An increase in the retardation factor, R, indicates that the solute is being adsorbed onto the sub-surface media as solute transport rate decreases (Leij and van Genuchten, 1999). An increase in the hydrodynamic dispersion, D, indicates more micro-mixing in the system. An increase in hydrodynamic dispersion results in the gradient of the response curve being lower as the solute transport is more widely spread. The first-order degradation impacts the final outlet concentration of the response curve and an increase in μ results mean the rate of degradation increases because some of the tracer has been lost due to biological degradation, adsorption, or photo-degradation and less than 100 % of the inlet concentration is achieved at the outlet. This is only the case for non-conservative tracers. There is a constraint on γ, the zero-order production term, as the production of the solute would have an upper limit based on the reaction or processes producing it.

Solving the transport equation for conservative and non-conservative tracers

When a tracer is conservative, it is neither degraded nor produced, this means that $\mu = \gamma = 0$ and the advective-dispersive transport takes the form given in Equation 2.36. The initial condition for Equation 2.36 is given by Equation 2.37. The two boundary conditions used in this case are the step-change in the conservative tracer in the feed to the system at time t=0, given by Equation 2.38 and the semi-infinite assumption given in Equation 2.39.

$$R\frac{\partial C}{\partial t} = D\frac{\partial^2 C}{\partial x^2} - u\frac{\partial C}{\partial x} \tag{2.36}$$

$$C(x, 0) = C_{initial} \tag{2.37}$$

$$\left(-D\frac{\partial C}{\partial x} + uC\right)\Big|_{x=0} = uC_{inlet} \tag{2.38}$$

$$\frac{\partial C}{\partial x}(\infty, t) = 0 \tag{2.39}$$

Under these conditions, Equation 15 can be solved analytically using the method developed by Lindstrom et al. (Lindstrom *et al.*, 1967) through a Laplace transformation. The solution can be found in Equation 2.40, where A(x, t) is a function of the tracer properties and fluid velocity and is presented in Equation 2.41.

$$C(x,t) = C_{intial} + (C_{inlet} - C_{initial}) * A(x,t) \tag{2.40}$$

$$A(x,t) = \frac{1}{2} erfc\left[\frac{Rx-ut}{2(DRt)^{1/2}}\right] + \left(\frac{u^2 t}{\pi DR}\right)^{1/2} exp\left[-\frac{(Rx-ut)^2}{4DRt}\right] -$$

$$\frac{1}{2}\left(1 + \frac{ux}{D} + \frac{u^2 t}{DR}\right) exp\left(\frac{ux}{D}\right) erfc\left[\frac{Rx+ut}{2(DRt)^{1/2}}\right] \tag{2.41}$$

In the case of a non-conservative tracer, it cannot be assumed that there is no degradation or production and so $\mu \neq \gamma \neq 0$ and the analytical solution of the transport equation is different than that of a conservative tracer. An analytical method developed by van Genuchten (van Genuchten, 1981), using Laplace transforms, was used to solve Equation 2.34 under non-conservative conditions. The initial condition and boundary conditions of the transport equation describing the non-conservative tracer are the same as that of the conservative tracer, but the analytical solution is different. The analytical solution is given in Equation 2.42 (van Genuchten, 1981) where A(x,t) is provided in Equation 2.43 and B(x,t) is provided in Equation 2.44.

$$C(x,t) = \left(C_{inlet} - \frac{\gamma}{\mu}\right) * A(x,t) + B(x,t) \tag{2.42}$$

$$A(x,t) = \frac{u}{u+v} * exp\left[\frac{(u-v)x}{2D}\right] erfc\left[\frac{Rx-vt}{2(DRt)^{1/2}}\right] + \frac{u}{u-v} exp\left[\frac{(v+u)x}{2D}\right] * erfc\left[\frac{Rx+vt}{2(DRt)^{1/2}}\right] +$$

$$\frac{u^2}{2\mu D} exp\left(\frac{ux}{D} - \frac{\mu t}{R}\right) * erfc\left[\frac{Rx+ut}{2(DRt)^{1/2}}\right] \tag{2.43}$$

$$B(x,t) = \left(\frac{\gamma}{\mu} - C_{inital}\right) * exp\left(-\frac{\mu t}{R}\right) * \left\{\frac{1}{2} erfc\left[\frac{Rx-ut}{2(DRt)^{1/2}}\right] + \left(\frac{u^2}{\pi RD}\right)^{1/2} * exp\left[-\frac{(Rx-ut)^2}{4DRt}\right] - \frac{1}{2}\left(1 + \frac{ux}{D} + \frac{u^2 t}{DR}\right) * exp\left(\frac{ux}{D}\right) * erfc\left[\frac{Rx-ut}{2(DRt)^{1/2}}\right]\right\} + \frac{\gamma}{\mu} + \left(C_{intial} - \frac{\gamma}{\mu}\right) * exp\left(-\frac{\mu t}{R}\right) \quad (2.44)$$

Factor *v* is given in Equation 2.45.

$$v = u * \left(1 + \frac{4\mu D}{u^2}\right)^{1/2} \quad (2.45)$$

Richard's Equation

Richard's equation is a partial differential equation which is used to describe unsaturated flow in a non-porous medium and is defined according to Equation 2.46 (Giraldi *et al.*, 2009). The relationship between pressure head (h), hydraulic conductivity (K) and water content (θ_w) are described according to van Genuchten-Mualem functions (Equation 2.47 and Equation 2.48) (van Genuchten, 1980). This equation is commonly used to describe the water flow in vertical flow CWs as the flow in these systems is often unsteady and unsaturated (Langergraber and Simunek, 2005). Richard's equation forms one of the partial differential equations in the HYDRUS Wetland module, executed in HYDRUS software (Langergraber and Simunek, 2005). Many researchers have made used of this model to successfully validate and investigate the processes taking place in CWs (Pálfy and Langergraber, 2014; Rizzo *et al.*, 2014).

$$\frac{\partial \theta_w}{\partial t} = +\frac{\partial}{\partial z}\left[K\left(\frac{\partial h}{\partial z} - 1\right)\right] \quad (2.46)$$

$$\begin{cases} \theta_w = \theta_r + \frac{\theta_s - \theta_r}{\left(1+|\alpha h|^{1/(1-m)}\right)^m} & , \quad h < 0 \\ \theta_w = \theta_s & , \quad h \geq 0 \end{cases} \quad (2.47)$$

$$\begin{cases} K = K_s \left(\frac{\theta_w - \theta_r}{\theta_s - \theta_r}\right)^{0.5} * \left[1 - \left(1 - \left(\frac{\theta_w - \theta_r}{\theta_s - \theta_r}\right)^{1/m}\right)^m\right]^2 & , \quad h < 0 \\ K = K_s & , \quad h \geq 0 \end{cases} \quad (2.48)$$

VART model

Variable residence time (VART) model was initially developed as a model for longitudinal dispersion and solute transport in streams (Deng and Jung, 2009). It is based on a 'double-

layer' conceptual model. The upper layer is dominated by advection-transient storage and the lower layer is a diffusion-dominated storage zone (Deng and Jung, 2009). The model is used for FWS wetlands because they have the same 'double layer' that is conceptualised for the VART model. Additionally, streams and FWS wetlands have similar transient storage zones (Martinez and Wise, 2003). The VART model has been used to compute the hydraulic residence time of wetlands filled with two different mediums and was able to accurately predict the RTD for design purposes (Zahraeifard and Deng, 2011). The model was combined with kinetic processes to simulate the removal of total phosphorus and ammonium (Aboukila and Deng, 2018), and BOD (Deng *et al.*, 2016) in FWS CWs and it was found that there was a good simulation of the three contaminants and the combined model is considered an efficient tool for designing CWs and understanding the effects of various processes and mechanisms on the treatment of wastewater in CWs (Deng *et al.*, 2016; Aboukila and Deng, 2018).

Convolution integral

The convolution integral can be used to describe the flow behaviour of a system. This model is not based on physical flow processes but rather the experimental data obtained directly from tracer studies. Sheridan et al. (2014) used the convolution integral to determine the rate constants for the degradation of winery effluent within a sub-surface flow CW (Sheridan, Glasser and Hildebrandt, 2014). These researchers found that because the rate constants obtained from the convolution integral are based directly on the RTD data, they were more accurate than the rate constants determined using the other models investigated. It is also possible to determine the conversion of a reactor, regardless of the degree of non-ideal behaviour, directly from the tracer information for first order reactions. The convolution integral, derived by Levenspiel (1999), is given in Equation 2.49 (Levenspiel, 1999).

$$C_{out}(t) = \int_0^t C_{in}(t - t')E(t')dt' \tag{2.49}$$

It can be shown that Equation 2.49 is an equivalent form of Equation 2.50.

$$C_{out}(t) = \int_0^t C_{in}(t')E(t - t')dt' \tag{2.50}$$

The concise form is given in Equation 2.51.

$$C_{out}(t) = C_{in} * E \tag{2.51}$$

The usefulness of this method arises from the fact that no reactor model is assumed. Rather, the unique data arising from the tracer test are directly utilised. This method was found to be significantly more accurate at modelling the reactor processes than the PFR or tanks-in-series.

2.10 Process Based Models

Process-based models are models which model multiple processes including kinetics, fluid flow, solute transport, the effect of plants, and biofilm growth. These models aim to give a better understanding of the interrelatedness of the processes taking place in CWs. The models require specific software, lots of computational power and an understanding of numerical modelling.

2.10.1 HYDRUS

The HYDRUS Wetland Module is considered to be one of the most comprehensive process-based wetland models (Langergraber, 2016). Implemented in the HYDRUS simulation software (Langergraber and J. Šimůnek, 2006), the model factors in fluid flow, solute transport, fluid uptake by plants, diffusion in the gaseous phase and a multi-component biokinetic model. Table 2.4 gives the individual models used for each of the processes described above. The HYDRUS Wetland module has been used to simulate the treatment of various types of wastewater including combined sewer overflow (Dittmer, Meyer and Langergraber, 2005; Henrichs, Langergraber and Uhl, 2007; Henrichs, Welker and Uhl, 2009; Pálfy *et al.*, 2016), grey water (Karlsson *et al.*, 2015), agricultural run-off (Smethurst *et al.*, 2014), and artificial wastewater (Rizzo *et al.*, 2014; Rizzo and Langergraber, 2016).

2.10.2 BIO_PORE

BIO_PORE is considered the other comprehensive process-based wetland model (Langergraber, 2016). This model is implemented in the COMSOL Multiphysics™ and factors modelled include a biokinetic model, solute transport, plant release of oxygen and uptake of nutrients, and the most novel element is the introduction of a biofilm sub-model. This sub-model was introduced in order to prevent unrealistic and unlimited growth of bacteria. Equations were also included for attachment and detachment of influent particulate components. Because of the biofilm sub-model it is able to predict the dynamic behaviour of CWs over a long period of time. Table 2.4 gives the gives the specific models and processes used in the BIO_PORE simulation.

***Table 2.4**: Breakdown of the different processes and models used in HYDRUS and BIO_PORE*

Process	HYDRUS	BIO_PORE
Flow	Richard's equation (saturated/unsaturated)	Darcy's equation (variable water table, saturated flow)
Solute transport	Advective-dispersive solute transport Adsorption	Advective-dispersive solute transport Adsorption
Biokinetic model	CWM1/CW2D	CWM1
Plant influence	Evapotranspiration Fluid uptake Uptake and release of substances	Evapotranspiration Fluid uptake Uptake and release of substances
Biofilm growth	None	Included

2.11 Research Objectives

The theory presented in this chapter highlights some of the techniques for understanding and modelling CWs. There are, however, a number of gaps including the existence of a model which factors in the biokinetic processes as well as accurately quantifying the hydraulic behaviour of a CW but does not require specific software, extensive computational power, and knowledge of numerical modelling. These gaps lead to this research study and in order to try and fill them, the following research objectives are presented:

f) The primary objective of this thesis is to develop a novel residence time distribution technique in order to improve the accuracy and the measurement and quantification of CW hydraulic flow behaviour.

g) To apply the technique to an existing biokinetic model, the International Water Association's constructed wetland model 1 (CWM1), to improve the accuracy of the predicted output concentrations of contaminants.

h) To modify the matrices of stochiometric coefficients and rate laws given in CWM1 to include a residence time distribution function.

i) To calibrate the model on a small-scale indoor reactor.

j) To validate the model on an established wetland.

Chapter 3: Materials and Methods

This chapter details the experimental procedures and analytical methods which were conducted in order to achieve the objectives stated in Section 2.10. Impulse response tracer studies were conducted on two systems, with the first being a set of vertical flow columns, located at the University of Linköping, Sweden. Tests were conducted on this system first, as the vertical flow columns have a simple configuration and no macrophytes, meaning the hinderances to ideal flow are fewer than in an established CW and therefore the hydraulic behaviour is likely closer to ideal plug-flow. The aim was to conduct tracer studies on a system whose hydraulic flow behaviour is close to ideal plug-flow and therefore allow for the proof of concept of the first technique presented in this thesis. The second set of impulse response tracer studies were conducted on a small-scale CW in Leipzig, Germany. Tests were conducted on this system to validate the first technique on an established system where wetland configuration and macrophyte distribution cause a deviation from ideal plug-flow.

Step-change response tracer tests were also conducted on the small-scale CW in Leipzig, Germany. In the step-change experiments conducted on this system a conservative tracer and a non-conservative tracer were used. The goal of these experiments was to determine the concentration-time response curves of each of the tracers and compare the data to a response which was simulated using the advective-dispersive transport equation. The aim of comparing the data from the experimental response curves and simulated response curves is to validate the second technique presented in this thesis.

3.1 Experimental Procedures

3.1.1 Impulse-response Tracer Studies:

Vertical column studies

Impulse-response tracer studies were conducted on three vertical flow columns, a picture of which can be seen in Figure 3.1. The system was located at the University of Linköping, Sweden. The columns were made of orange PVC and covered with a lid made of the same material. The packing material of the columns was pea gravel which had a diameter of 2 mm-8 mm and a void fraction of 0.36. The columns were identical in size with the dimensions being 0.15 m x 0.4 m (d x h). Each column was filled with the packing media to a height of 0.37 m. The system consisted of two ports, the inlet port at a height of 0.04 m above the base and the

outlet port at a height of 0.37 m above the base. At the inlet and outlet ports, flexible transparent tubing with an internal diameter of 0.02 m was attached. There was ~20 cm of tubing between the inlet port and the feed pump, and ~20 cm from the outlet port to where water was collected. The height of the outlet port determined the height of the water level, which was therefore also at 0.37 m. The water volume of the system was 2.16 l. A peristaltic pump was used to deliver water to the columns at a continuous and consistent flow rate of 31 ml/min. The impulse-response tracer studies were conducted one at a time on the individual vertical flow columns.

Figure 3.1*: Picture of the vertical flow gravel columns on which impulse-response tracer studies were conducted.*

A medical syringe was used to inject tracer into the inlet of the system at a time of $t = 0$. Uranine was used as a tracer. 10 ml of 10 ppm tracer was instantaneously injected into the inlet of the system. A needle was used to pierce the inlet pipe so that tracer could be injected as close to the inlet port as possible, thus minimising mixing before entering the column. The injection site was closed after injection to prevent leaking. Based on the inlet flow rate and volume of the system, the nominal residence time in these impulse-response tracer tests was 70 minutes. The duration of the test was long enough for the concentration of the tracer to reach background concentrations; this took 280 minutes. 4 ml of sample was taken every 4 minutes and stored in a plastic tube until analysis. Samples were analysed within 20 minutes of being taken.

Small-scale constructed wetland

Impulse-response tracer studies were conducted on a horizontal-sub-surface flow (HSSF) constructed wetland (a picture of which is shown in Figure 3.2). This system was located inside a greenhouse at the Hemholtz Centre for Environmental Research – UFZ, in Leipzig Germany. The packing material of the wetland was pea gravel with a diameter of 2 mm-8 mm and a void

fraction of 0.36. The wetland dimensions were 1 m x 0.21 m x 0.15 m (L x H x W). The system was planted with *Juncus effuses*. The wetland consisted of one inlet port at the height of the gravel surface, 21cm from the base, and one outlet port 1.5 cm from the base of the bed. A syphon breaker was used at the wetland outlet for level control. PVC 90° 3-way ball valves were placed on the inlet and outlet lines for tracer injection and sampling. A schematic of the experimental setup is shown in Figure 3.3.

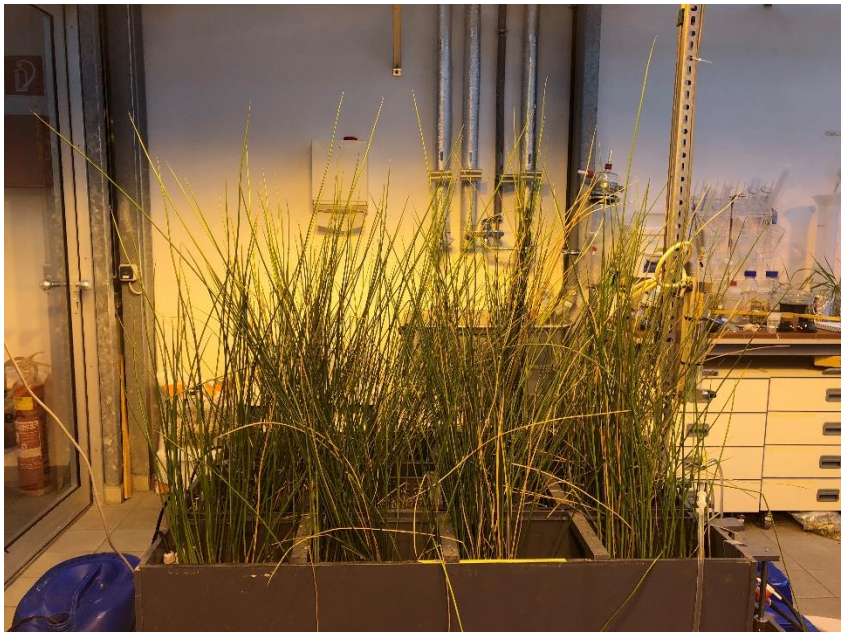

Figure 3.2*: Picture of the HSSF CW on which impulse-response and step change tracer studies were conducted*

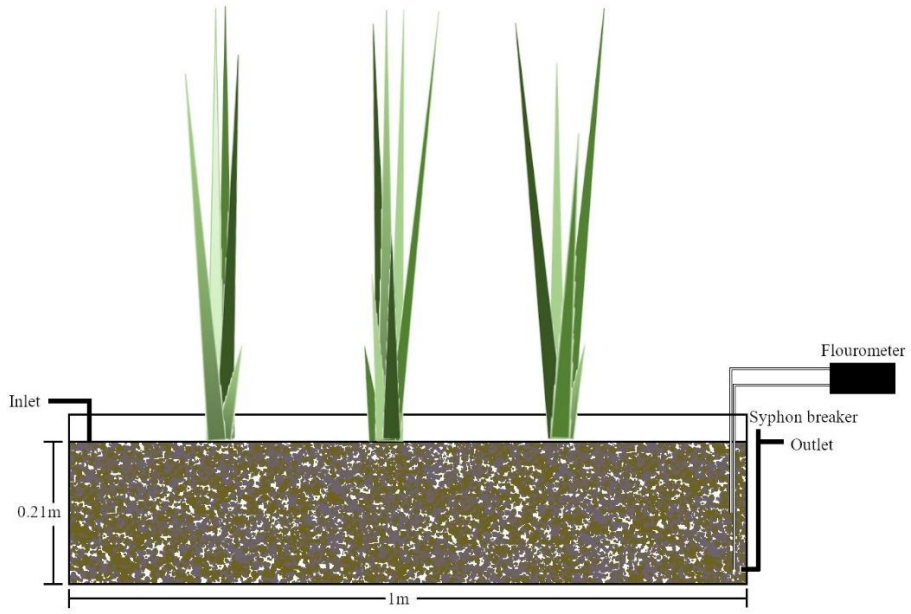

***Figure 3.3**: Schematic of the HSSF CW on which impulse-response and step change tracer studies were conducted*

A medical syringe was used to inject tracer into the inlet of the system at a time of $t = 0$. Uranine was used as a tracer. 10 ml of 3 x 10^4 ppm tracer was instantaneously injected. The syringe tip was inserted into the open end of the 90° 3-way ball valve, the ball valve was opened to allow 3-way flow, and the tracer was injected. The ball valve was returned to the original position and the syringe was removed. Based on the inlet flow rate and volume of the system, the nominal residence time of the system in these impulse-response tracer tests was 4 hours. The test was conducted until the concentration of tracer reached background concentrations.

3.1.2 Step change Response Tracer Studies

Step change tracer studies were conducted on a horizontal-sub-surface flow (HSSF) constructed wetland (a picture of which is shown in Figure 3.2). This system was inside a greenhouse at the Hemholtz Centre for Environmental Research – UFZ, in Leipzig Germany. The packing material of the wetland was pea gravel with a diameter of 2 mm-8 mm and a void fraction of 0.36. The wetland dimensions were 1 m x 0.21 m x 0.15 m (L x H x W). The system was planted with *Juncus effuses*. The wetland consisted of one inlet port at the height of the gravel surface and one outlet port 1.5 cm from the base of the bed. A syphon breaker was used at the wetland outlet for level control. A schematic of the experimental setup is shown in Figure 3.3.

The step-change tracer study was a combined study with a conservative tracer and a non-conservative tracer. Sodium benzoate was used as the non-conservative tracer, specifically because benzoate $(C_7H_5O_2)^-$ is biodegradable under both aerobic and anaerobic conditions (Salanitro *et al.*, no date; Wibbertmann *et al.*, 2005). Uranine was used as the conservative tracer.

Prior to running the step-change experiment, the wetland was flushed with distilled water and TMS3 ,a tracer metal solution, dissolved in distilled water (Kuschk, 1991). The concentration of TMS3 was set such that the ion concentration was the same as the expected ion concentration of the step-change experiment. This was done to acclimatise the microbial groups in the wetlands to the expected ionic concentration which leads to a stable microbial transformation of chemical components, before switching the feed to the inlet solution, which contained tracer solution, at $t = 0$ (which was 16:35 CET). The inlet solution consisted of uranine, sodium benzoate, sodium acetate and ammonium nitrate in distilled water. The use of these compounds was to provide more than one organic feed substrate to the wetlands, in the form of sodium acetate and sodium benzoate, and to provide a nitrogen source as well, in the form of ammonium nitrate. The inlet concentrations of each of these can be found in Table 3.1. The inlet concentrations in this table are the measured concentrations of the ions but were determined based on the inlet concentrations of the compounds. Benzoate, or benzoic acid, does not have a high solubility in water so sodium benzoate is used to introduce it into the system as it has a much higher solubility (Jorge, 2003). A syringe pump was used to feed the sodium acetate and sodium benzoate solutions into the feed line to prevent degradation of the organic carbon in a feed tank. The experiments were run with a theoretical residence time of 72 hours (with an inlet flow rate of 0.23 l/hour) to ensure enough time for the degradation of organic carbon. The duration of the step-change tracer study was three times the theoretical residence time to ensure steady-state operation was achieved (Kadlec and Wallace, 2009). Samples were collected manually for the benzoate concentration, at the outlet and inlet, at the sample points. This was done three times a day at 07:00, 14:00 and 21:00 for the duration of the experiment. An inline fluorometer was used to determine uranine concentration at the outlet.

Table 3.1. *Inlet concentrations of compounds used in the tracer comparing a conservative and non-conservative tracer*

Compound	Concentration
Sodium (mg/L)	24.2
Acetate (mg/L)	13.4
Benzoate (mg/L)	82.1
Ammonium (mg/L)	67.0
Nitrate (mg/L)	201.6
Uranine (ppb)	40

The concentration of acetate, ammonium and nitrate were monitored at the outlet and used as an extra indicator of steady state but were not used for test interpretation.

3.2 Analytical Techniques

3.2.1 Impulse-response – Vertical Column Studies

The samples taken for the impulse response tracer studies conducted on vertical flow columns in Linköping, Sweden were analysed using a FluoroSELECT® fluorometer (Sigma-Aldrich). To calibrate the fluorometer two standards are required, one blank and another of known concentration. The second standard used was 100 ppb. The calibration was done automatically by the FluoroSELECT® fluorometer. Standards of 25 ppb, 50 ppb and 100 ppb were kept on hand and used between every five samples to ensure the calibration still held. Samples were placed in 0.2 µl PCR tubes and then into the fluorometer. Each sample was analysed three times.

3.2.2 Impulse-response – Small Scale Constructed Wetland

To analyse the uranine concentration in the impulse-response tracer studies conducted on a small-scale constructed wetland, a GGUN-FL30 fluorometer was used for automatic, inline detection of uranine at the outlet of the wetland. A sampling rate of 3 minutes was selected, and the data was recorded by a datalogger. The fluorometer drew water from inside the wetland close to the outlet, it was pumped through the detection chamber of the fluorometer and then back into the wetland at a rate such that the concentration of the water was not affected.

3.2.3 Step change – Small Scale Constructed Wetland

To analyse the uranine concentration in the step-change tracer studies conducted on a small-scale constructed wetland, a GGUN-FL30 fluorometer was used for automatic, inline detection

of uranine at the outlet of the wetland. A sampling rate of 5 minutes was selected, and the data was recorded by a datalogger. The fluorometer drew water from a point inside the wetland, close to the outlet, it was pumped through the detection chamber of the fluorometer and then back into the wetland at a rate such that the concentration of the water was not affected.

For the analysis of benzoate in the small-scale constructed wetland, a volume of 5 ml was taken using a syringe for each manual sample and was filtered using a 0.2 µm syringe filter. Each sample was separated into two vials: one for benzoate analysis and one back-up sample. The back-up samples were stored in a dark space to prevent UV degradation of uranine and at -20°C. The samples to be analysed for benzoate were frozen at - 20 °C until analysed using ion chromatography (Thermo Scientific™ – Dionex™ ICS-5000^{+} HPIC™ System).

3.3 Software Used

3.4.1 R Software

R is a programming language and environment for statistical computing and graphics (R Core Team, 2020). R version 4.0.2 (2020-06-22), nickname 'Taking Off Again', on platform x86_64-w64-mingw32 was used for the data analysis of the impulse-response tracer studies conducted in Leipzig, Germany and Linköping, Sweden, as well as the step-change experiments conducted in Leipzig, Germany. RStudio is an add-on to R and provides a user-friendly graphical interface for ease of use.

R was used for non-linear least-squares regression analysis. The package used was 'stats' and the function used was 'nls' (R Core Team, 2020). The default algorithm for the 'nls' function is Gauss-Newton algorithm (R Core Team, 2020).

The package 'ggplot2' was used to generate the figures (Chang, 2014; Wickham, 2016). The code used to generate the figures are given in Appendix A, Appendix E, Appendix F, Appendix G, Appendix I, and Appendix L.

Chapter 4: Development of the mathematical techniques for modelling CW systems

Section 4.2 was presented at the 8th International Symposium of Wetland Pollutant Dynamics and Control, in Aarhus, Denmark (June 2019). (Stephenson, R., Sheridan, C. and Kappelmeyer, U. (2019, June 17-21) *Development of a residence time distribution technique combined with CWM1* [Conference presentation]. 8th International Symposium of Wetland Pollutant Dynamics and Control, in Aarhus, Denmark). The contribution of the co-authors towards the work is primarily that of supervision or collaboration and the experimental work and write-up was conducted by the author of this thesis.

Section 4.3 has been published in Science of the Total Environment and was peer reviewed prior to publication (Stephenson, R., Sheridan, C. and Kappelmeyer, U. (2020) 'A curve-shift technique for the use of non-conservative organic tracers in constructed wetlands', *Science of The Total Environment*. Elsevier B.V., 752, p. 141818. doi: 10.1016/j.scitotenv.2020.141818). The contribution of the co-authors towards the work is primarily that of supervision or collaboration and the experimental work and write-up was conducted by the author of this thesis.

4.1 Introduction

The effectiveness of CWs in reducing the contaminants in wastewater, through the various chemical, biological, and physical processes which take place, is strongly dependent on the hydraulic behaviour of the system. One way of assessing this behaviour is to conduct residence time distribution (RTD) studies (Headley and Kadlec, 2007). In these studies, a tracer is added at the inlet of the wetland and the concentration at the outlet is continuously monitored. Numerical methods are applied to the results of these studies in a set of characteristics that can be used to describe the hydraulic behaviour of the flow through constructed wetlands (Bonner *et al.*, 2017). The current numerical models that are applied to the data from RTD studies were outlined in the literature review (Section 2.8.4). In most of the hydraulic models presented, an assumption is made about the nature of the flow in the system (plug flow, dispersed flow, etc.), and these models are further based on the assumption that the tracer used in the experiment is

not adsorbed, degraded, or accumulates. It has been known for many years that these assumptions are to a greater or lesser extent erroneous for CWs. The heterogenous wetland matrix, the presence of macrophytes (and their continuously changing root structure), together with the physical design configuration can lead to dead zones, short circuiting of the flow, and non-ideal mixing. This means that the flow through the CW can be quite far from ideal. Additionally, the second assumption of conservative tracer behaviour is also not true. Some tracers, such as the uranine, are prone to adsorption in the presence of organic matter or photodegradation, and ionic tracers can result in haloclines which also result in errors in calculations.

As a result of the errors and non-ideal flow conditions listed, two mathematical techniques are presented in this chapter which are not based on these erroneous assumptions.

4.2 Methods-of-Moments Adaptation

The first of the two techniques described here is based on the method-of-moments model and uses data from an impulse-response study. For the methods-of-moments model, no assumption is made about the flow behaviour. This method results in a mean residence time which is used as a representation of the average residence time of all particles of fluid in the system. This can, however, lead to an oversimplification of the hydraulic behaviour. There is a distribution of times that the molecules spend in the reactor. Some may short-circuit through the system and have a residence time much shorter than the mean residence time, while others may get caught in a dead zone and spend a much greater amount of time in the system. These varying times the particles spend in the system affects the reaction time of these individual molecules and consequently, this affects the composition of the outlet stream. The single mean residence time value, from the method-of-moments technique, is most often used for reactor models such as the PFR or CSTR to determine rate constants or predict the extent of contaminant removal in the system. The effect of time on such systems cannot be accurately described with one single mean residence time, especially in non-ideal reacting systems. The model being developed and described in this study can be used to more accurately account for the effect of time on a biological system, or any reactor system, by making use of multiple residence times for specific fractions of the fluid.

The technique presented in this section is based on the concept that there are multiple flow paths in constructed wetlands, each of which has its own residence time. These flow paths

'carry' multiple tiny pockets of fluid which behave as micro-batch reactors. To account for transient and dead zones it can be assumed that when a micro-batch reactor enters a dead zone it remains in place for some time and then re-enters one of the flow paths, moving through the transient zone on the way in, and out, of the dead zone. The residence time of molecules entering and leaving the transient and dead zones will be longer than that of the rest of the molecules in the flow path. There are therefore multiple micro-batch reactors moving along the wetland, although there is no requirement for this batch to flow through the reactor in an ideal manner. As the volume of these micro-batch reactors tends to 0, the batch system tends towards a molecular size. The assumption of batch reactor is made so that each flow path can be analyzed and modelled on its own, irrespective of the reaction rate order.

The design equation of a simple batch reactor with a first-order reaction taking place (Equation 4.1) can be solved to make the outlet concentration the subject of the formula, as is given in Equation 4.2, and time (t) is accounted for in the exponential term. This is the base equation which is to be expanded through the model development presented here. In an ideal reactor, the space-time (as defined by 2.22) could be used to indicate how much time the fluid elements spend inside a system. However, very few reactors behave ideally and so the non-ideal nature of systems must be accounted for.

$$\frac{dC}{dt} = r(C) = -kt \tag{4.1}$$

$$C_{out} = C_{in}e^{-kt} \tag{4.2}$$

To describe and develop the concept it was assumed that the water flow in a CW can be described by two flow paths along the length of wetland, each with half the fluid volume of the system, so two micro-batch reactors had to be modelled. The area under the $E(t)$ curve is then divided into two portions as shown in Figure 4.1. The code used to generate Figure 4.1 can be found in Appendix A. There is an average amount of time that the fluid elements of each portion spend in the reactor, this is defined as tj. The definition of t_m (as shown in Chapter 2) can then be extended to apply to Portion 1 and Portion 2 under the curve and is given by Equations 4.3 and Equation 4.4, respectively. The fraction of the area under the curve for each portion is defined as γ_j and can be conceptualised as a fraction of the total volume of the reactor. γ_1 and γ_2 are described by Equations 4.5 and 4.6, respectively and are defined as weighting factors. The sum of the weighting factors is equal to 1. The weighting factors make it possible to

determine the contribution that each portion makes to the hydraulic flow behaviour of the system. For example, if the areas are each 50% of the total area, they would have a weight factor of 0.5 each and contribute equally to the hydraulic behaviour of the system. From this, it can be said that fraction γ_j, of the fluid passing through the reactor, spends an average time of t_j within the system. Each portion is assumed to behave as its own batch reactor moving along the length of the wetland. Equation 4.2, the solved batch reactor design equation, is then adapted to include the two portions each with their own mean residence time and weight factor. A summation term is included to account for the two portions, and this is given by Equation 4.7.

***Figure 4.1**: E(t) response curve divided into two portions, each with an area of 0.5*

$$t_1 = \frac{\int_{T0}^{T1} tE(t)dt}{\int_{T0}^{T1} E(t)dt} \tag{4.3}$$

$$t_2 = \frac{\int_{T1}^{T2} tE(t)dt}{\int_{T1}^{T2} E(t)dt} \tag{4.4}$$

$$\gamma_1 = \int_{T0}^{T1} E(t)dt \tag{4.5}$$

$$\gamma_2 = \int_{T1}^{T2} E(t)dt \tag{4.6}$$

$$C_{out} = \gamma_1 C_{in} e^{-kt_1} + \gamma_2 C_{in} e^{-kt_2} = \sum_{j=1}^{2} \gamma_j \, C_{in} e^{-kt_j} \tag{4.7}$$

The concept described above can be expanded to include 4 portions as is visually represented in Figure 4.2a. Each of the 4 portions represents a flow path carrying micro-batch reactors with

a specific mean residence time and weight factor. A larger number of portions can also be considered, for example, 10 portions (Figure 4.2b), each with a specific mean residence time and weight factor. The total outlet concentration of the system can then be calculated as a sum of the effect of each portion or flow path. This is given in Equation 4.8 for 4 portions and Equation 4.9 for 10 portions. A more general form is expressed in Equation 4.10 where there are 'n' flow paths in the system and therefore 'n' portions under the curve.

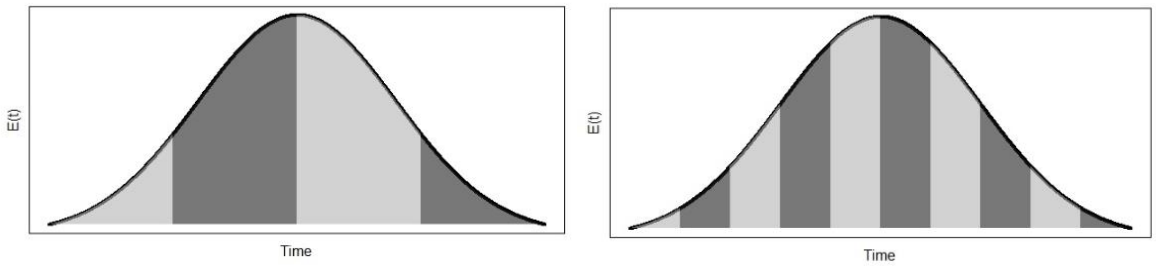

***Figure 4.2**: a) E(t) curve divided into 4 portions. b) E(t) curve divided into 10 portions*

$$C_{out} = \sum_{j=1}^{4} \gamma_j \, C_{in} e^{-kt_j} \tag{4.8}$$

$$C_{out} = \sum_{j=1}^{10} \gamma_j \, C_{in} e^{-kt_j} \tag{4.9}$$

$$C_{out} = \sum_{j=1}^{n} \gamma_j \, C_{in} e^{-kt_j} \tag{4.10}$$

This kinetic and hydraulic modelling are integrated, and this model can be generalised to include non-linear kinetic rates of reaction.

4.3 The curve-shift Technique

The second of the techniques is based on the advective-dispersive transport equation and addresses the issue regarding the assumption of tracer conservation in RTD studies. Tracers are not always conserved across the system, as was mentioned in the literature review. It is also the case that when conducting RTD studies in the field, tracers can be difficult to recover or remove from the environment once the tracer study is over. In order to prevent environmental issues, equipment to recover the material is required which increases the overall cost of conducting the tracer studies in the field. In most cases, even partial recovery of a tracer is not feasible, and the tracers remain in the environment potentially posing problems. To avoid these challenges, it is possible to consider using a non-conservative tracer for conducting RTD studies. The advantage of these types of tracers is that they pose less of an environmental

concern as they typically degrade with time and thus do not remain in the environment after the completion of the tracer study. The aim of the curve-shift technique is to develop a technique that makes use of the degradation predictions and an understanding of transport phenomena to alter the response curve of a non-conservative tracer to give the same information as the response curve of a conservative tracer. In doing so, this would allow for the accurate estimation of hydraulic behaviour parameters for tracers which are not conservative. If achieved, this could make it feasible to use non-conservative tracers in hydraulic tracer studies of constructed wetlands and reduce the environmental footprint of these studies. A technique of this type has rarely been achieved for a biodegradable non-conservative tracer up to this point.

The advective-dispersive transport equation with retardation and decay quantifies the transport of a single solute which can undergo decay and retardation. This equation is based on the assumptions outlined in the literature review. This partial differential equation is given in Equation 4.11 and describes the transport of a single solute along the length of a reactor, in one dimension. It can be used to describe the movement of a chemical tracer in the sub-surface media of a HSSF CW but not for other reactor types as it is assumed that the flow is through porous media (Wynn and Liehr, 2001).

$$R\frac{\partial C}{\partial t} = D\frac{\partial^2 C}{\partial x^2} - u\frac{\partial C}{\partial x} - \mu C + \gamma \tag{4.11}$$

$$R = 1 + \frac{\rho_b K_d}{\varepsilon} \tag{4.12}$$

To show the effect of retardation (R), hydrodynamic dispersion (D), and first-order decay (μ) on the residence time distribution response curve, Equation 4.11 has been solved and simulated for a series of time values (0-1000 in steps of 10) in a hypothetical system. The results of this are shown in Figure 4.3 as an example of the way the equations work (full results based on a real system are presented in Section 7.3). The code used to generate Figure 4.3 can be found in Appendix A. For all cases shown here the velocity of the fluid was assumed to be 0.01 m/s, the initial concentration was assumed to be 0, the inlet concentration was assumed to be 1 (normalised) and the length of the system (x) was assumed to be 1 (normalised). For materials that are non-sorbing R is equal to 1. This indicates that the transport of the solute is the same as that of the water (Boy-Roura *et al.*, 2018). An increase in the retardation factor, R, results in the slowing down of the response curve as the solute is adsorbed onto the sub-surface media

and the solute transport rate decreases (Leij and van Genuchten, 1999). An increase in the hydrodynamic dispersion, D, indicates more micro-mixing in the system. This would result in the solute being more dispersed down the length of the reactor. An increase in D would speed up the time in which the tracer arrives at the outlet initially but would not necessarily speed up the time it takes for the inlet concentration to be reached. An increase in hydrodynamic dispersion results in the gradient of the response curve being lower as the solute transport is more widely spread. The first-order decay (μ) impacts the final outlet concentration of the response curve. An increase in the rate of degradation results in the steady-state outlet concentration being lower than 1. This is because some of the tracer has been lost due to biological degradation, adsorption, or photo-degradation and less than 100 % of the pulse entering the systems (by mass) exits the system in the outlet flow. This is only the case for non-conservative tracers. There is a constraint on γ, the zero-order production term, as the production of the solute would have an upper limit based on the reaction or processes producing it.

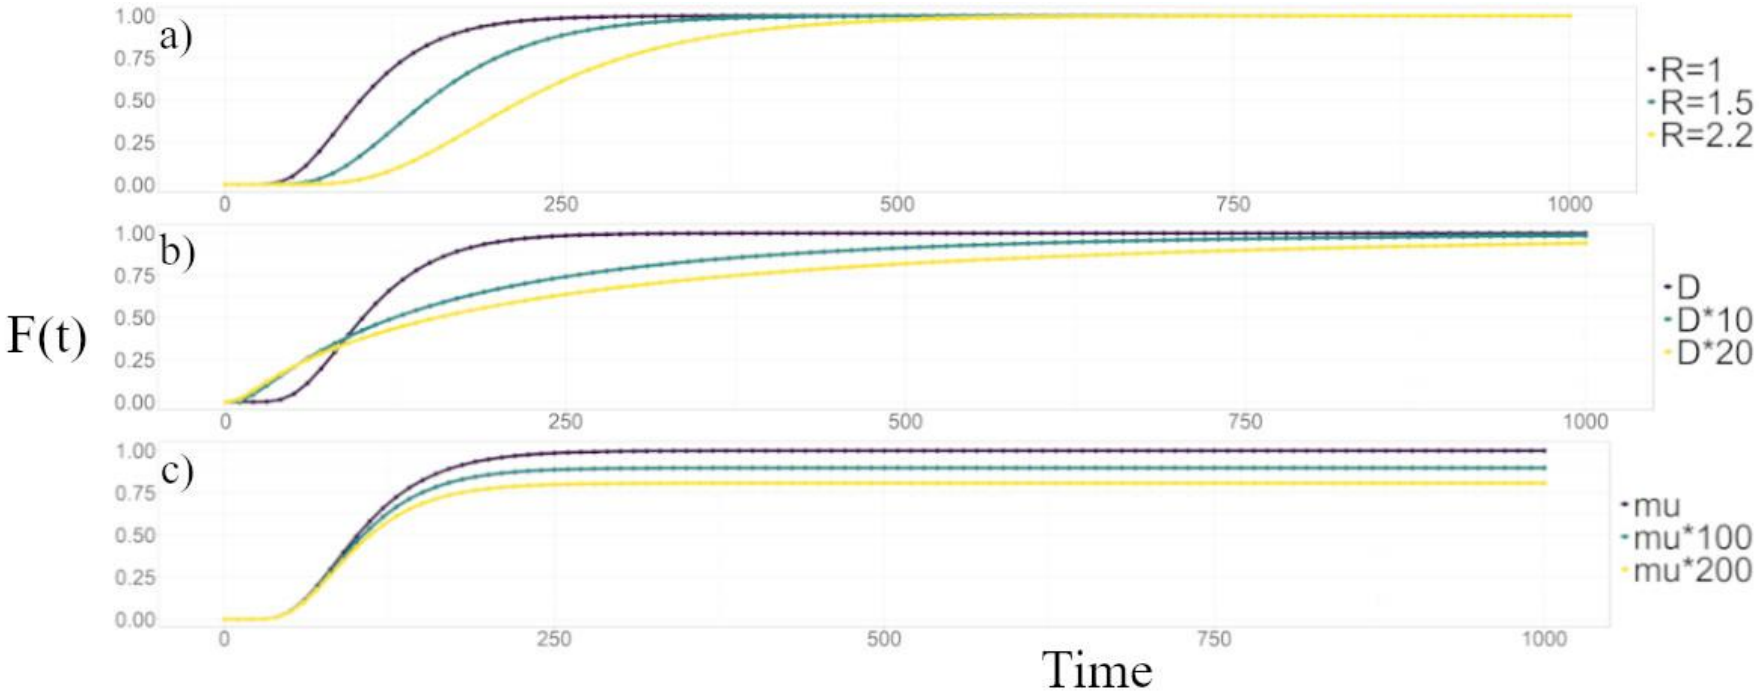

Figure 4.3. *Effect of retardation (a), dispersion (b) and decay (c) on the response curve of a residence time distribution study*

4.3.1 Solving the Transport Equation for Conservative and Non-conservative Tracers

In the case of the conservative nature of the conventional tracer $\mu = \gamma = 0$ and the transport equation takes the form given in Equation 4.13. The initial condition for Equation 4.13 is given by Equation 4.14. The two boundary conditions used in this case are the step-change in the conservative tracer in the feed to the system at time t=0, given by Equation 4.15 and the semi-infinite concentration assumption given in Equation 4.16.

$$R\frac{\partial C}{\partial t} = D\frac{\partial^2 C}{\partial x^2} - u\frac{\partial C}{\partial x} \tag{4.13}$$

$$C(x,0) = C_{initial} \tag{4.14}$$

$$\left(-D\frac{\partial C}{\partial x} + uC\right)\Big|_{x=0} = uC_{inlet} \tag{4.15}$$

$$\frac{\partial C}{\partial x}(\infty, t) = 0 \tag{4.16}$$

Under these conditions, Equation 4.13 can be solved analytically using the method developed by Lindstrom et al. (Lindstrom *et al.*, 1967) through a Laplace transformation. The solution can be found in Equation 4.17, where A(x, t) is a function of the tracer properties and fluid velocity and is presented in Equation 4.20.

$$C(x,t) = C_{intial} + (C_{inlet} - C_{initial})\,A(x,t) \tag{4.17}$$

$$A(x,t) = \frac{1}{2}erfc\left[\frac{Rx-ut}{2(DRt)^{1/2}}\right] + \left(\frac{u^2 t}{\pi DR}\right)^{1/2} exp\left[-\frac{(Rx-ut)^2}{4DRt}\right] -$$

$$\frac{1}{2}\left(1 + \frac{ux}{D} + \frac{u^2 t}{DR}\right) exp\left(\frac{ux}{D}\right) erfc\left[\frac{Rx+ut}{2(DRt)^{1/2}}\right] \tag{4.20}$$

For the case of a non-conservative tracer, it cannot be assumed that there is no degradation or production and so $\mu \neq \gamma \neq 0$ and the analytical solution of the transport equation is different to that of a conservative tracer. An analytical method derived by van Genuchten (van Genuchten, 1981), using Laplace transforms, was used to solve Equation 4.13 under non-conservative conditions. The initial condition and boundary conditions of the transport equation describing the non-conservative tracer are the same as that of the conservative tracer,

but the analytical solution is different. The analytical solution is given in Equation 4.21 (van Genuchten, 1981) where $A(x,t)$ is provided in Equation 4.22 and $B(x,t)$ is provided in Equation 4.23.

$$C(x,t) = \left(C_{inlet} - \frac{\gamma}{\mu}\right) A(x,t) + B(x,t) \tag{4.21}$$

$$A(x,t) = \frac{u}{u+v} exp\left[\frac{(u-v)x}{2D}\right] erfc\left[\frac{Rx-vt}{2(DRt)^{1/2}}\right] + \frac{u}{u-v} exp\left[\frac{(v+u)x}{2D}\right] erfc\left[\frac{Rx+vt}{2(DRt)^{1/2}}\right] + \frac{u^2}{2\mu D} exp\left(\frac{ux}{D} - \frac{\mu t}{R}\right) erfc\left[\frac{Rx+ut}{2(DRt)^{1/2}}\right] \tag{4.22}$$

$$B(x,t) = \left(\frac{\gamma}{\mu} - C_{inital}\right) * exp\left(-\frac{\mu t}{R}\right)\left\{\frac{1}{2} erfc\left[\frac{Rx-ut}{2(DRt)^{1/2}}\right] + \left(\frac{u^2}{\pi RD}\right)^{1/2} exp\left[-\frac{(Rx-ut)^2}{4DRt}\right] - \frac{1}{2}\left(1 + \frac{ux}{D} + \frac{u^2 t}{DR}\right) * exp\left(\frac{ux}{D}\right) erfc\left[\frac{Rx-ut}{2(DRt)^{1/2}}\right]\right\} + \frac{\gamma}{\mu} + \left(C_{intial} - \frac{\gamma}{\mu}\right) * exp\left(-\frac{\mu t}{R}\right) \tag{4.23}$$

Factor v is given in Equation 4.24:

$$v = u\left(1 + \frac{4\mu D}{u^2}\right)^{1/2} \tag{4.24}$$

4.4 Conclusion

This chapter shows the development, and provides the basis, for two techniques which can be used to progress hydraulic modelling efforts for CWs. One is an adapted form of the methods-of-moments technique and the other is a curve-shift technique based on the advective-dispersive transport equation. However, these two techniques must be combined with kinetic models. This is discussed in the following two chapters.

Chapter 5: Introduction of a biokinetic model into the mathematical techniques

Section 5.2 was presented at the 8th International Symposium of Wetland Pollutant Dynamics and Control, in Aarhus, Denmark (June 2019). (Stephenson, R., Sheridan, C. and Kappelmeyer, U. (2019, June 17-21) *Development of a residence time distribution technique combined with CWM1* [Conference presentation]. 8th International Symposium of Wetland Pollutant Dynamics and Control, in Aarhus, Denmark). The contribution of the co-authors towards the work is primarily that of supervision or collaboration and the experimental work and write-up was conducted by the author of this thesis.

Section 5.3 has been published in Science of the Total Environment and was peer reviewed prior to publication (Stephenson, R., Sheridan, C. and Kappelmeyer, U. (2020) 'A curve-shift technique for the use of non-conservative organic tracers in constructed wetlands', *Science of The Total Environment*. Elsevier B.V., 752, p. 141818. doi: 10.1016/j.scitotenv.2020.141818). The contribution of the co-authors towards the work is primarily that of supervision or collaboration and the experimental work and write-up was conducted by the author of this thesis.

5.1: Introduction

The chemical, biological, and physical processes which contribute to the transformation of contaminants in the wastewater entering CWs take place simultaneously and influence one another. This inter-relatedness of processes is what makes these systems challenging to model and is still the subject of CW modelling research (Meyer *et al.*, 2015). Before the modelling of individual kinetic processes can be done, an understanding of the specific processes and how they occur is required. Initial modelling of CWs was based on 'black-box' approaches, which relied on correlations between inlet and outlet concentrations of pollutants rather than the understanding of the processes which contributed to the degradation (J L G Kumar and Zhao, 2011). Modelling of CWs has progressed to include models which are based, not only on the understanding of the individual processes but the inter-relatedness of all the processes. One

such model that aims to achieve this is Constructed Wetlands Model No 1 (CWM1), which focuses on the interrelatedness of biokinetics (Langergraber, Rousseau, *et al.*, 2009).

As described in Chapter 2, the CWM1 is a biokinetic model which models the degradation and production of 16 contaminants (soluble and particulate) via 17 reactions/processes (Langergraber, Rousseau, *et al.*, 2009). The model is set up in two matrices: one with the rate law for each reaction and one that connects each of the contaminants to the reaction rates by the use of stoichiometric coefficients. These two matrices were presented in Section 2.7.2. The CWM1 biokinetic model is comprehensive and the components modelled include organic matter, nitrogen species, sulfur species and bacterial function groups (Langergraber, Rousseau, *et al.*, 2009). However, this model is purely kinetic and does not consider the hydraulic behaviour of a CW. Kinetic modelling techniques rely on reaction time, but reaction time is a function of the hydraulic behaviour of the system. If the reaction time is quantified incorrectly, a kinetic model will not give accurate results, regardless of how detailed and comprehensive it may be. . It cannot be said that reaction time relies only on the hydraulic behaviour of the system and the importance of mixing and local concentration must not be forgotten. Given the non-ideal flow nature of these CWs, kinetic modelling techniques must be combined with accurate hydraulic modelling techniques for effective modelling of the system. In this chapter, a discussion is presented detailing how the CWM1 biokinetic model can be combined with the two techniques for interpreting the data of hydraulic tracer studies, as described in Chapter 4.

5.2 Adapted Method-of-moments technique

The first part of the adapted method-of-moments technique was presented in Section 4.2 and this formed the hydraulic flow modelling part of the technique. For effective modelling of reactors, a kinetic model is also required. The aim of this section of the thesis is to demonstrate how a multi-component, multi-process, kinetic model (such as the CWM1) can be incorporated into the adapted method-of-moments technique.

In the CWM1 model, the reaction rate matrix is a 1 x 17 matrix in which each column gives the reaction rate of one process. The dot product of the reaction rate matrix and the stochiometric coefficient matrix is a 16 x 1 matrix. Each row of the resultant matrix gives the rate of transformation of a specific species. To incorporate the CWM1 model into the adapted

method-of-moments technique, a slight adaptation was made to the structure of the matrices. No changes were made to the reactions rate laws or stochiometric coefficients. The reaction rate matrix was expanded from a 1 x 17 matrix to a 17 x 17 matrix in which each row is identical, and each column still gives the reaction rate of one process, but this is repeated 17 times, for 17 rows. The dot product of this adapted matrix and the original CWM1 stochiometric coefficients matrix is a 16 x 17 matrix, the component transformation rate matrix. In this resultant matrix, at position $R_{i,l}$ the rate transformation of component *'i'* in process *'l'* is given. An example of element $R_{3,5}$ of the component transformation rate matrix is presented in Equation 5.1 (Langergraber, Rousseau, *et al.*, 2009). As Equation 5.1 is a rate of chemical transformation, it is denoted $r_{3,5}$. Fermentation products, such as acetate, (S_A), (which is component 3 in the CWM1) are a substrate for the anoxic growth of heterotrophic bacteria (which is process 5 in the CWM1). The rate at which fermentation products, such as acetate, are consumed during the anoxic growth of heterotrophic bacteria is presented in Equation 5.1. In the component transformation rate matrix, the rate at which a specific component ($i = 1,2,3\ldots,16$) is transformed in a specific process ($l = 1,2,3,\ldots,17$) can be identified. In this way, each component is linked directly with each process. For cells where the coefficient matrix has been left blank in the CWM1, a zero value is used in the matrix dot product. The rate at which each component is degraded in each specific process in the CWM1 is given in Appendix B. The important point to take from this is that it is possible to identify the rate at which a specific component is transformed in a specific process, from the multi-component, multi-process biokinetic model and this makes it possible to work with the individual rates, not just the rate at which the component is transformed in the system as a whole. Being able to work with the individual rates is important for incorporating the biokinetic model into the adapted method-of-moments technique.

$$R_{3,5} = \left(-\frac{1}{Y_H}\right) n_g \, \mu_H \left[\frac{S_A}{K_{SA}+S_A}\right]\left[\frac{S_A}{S_F+S_A}\right]\left[\frac{K_{OH}}{K_{OH}+S_O}\right]\left[\frac{S_{NO}}{K_{NOH}+S_{NO}}\right]\left[\frac{S_{NH}}{K_{NHH}+S_{NH}}\right]\left[\frac{K_{H2SH}}{K_{H2SH}+S_{H2S^*}}\right] X_H \qquad (5.1)$$

The adapted method-of-moments technique, presented in Section 4.2, has been developed assuming first-ordered reaction rates with first-order rate constants. Currently the individual rates are not first-order but linearisation techniques are required to achieve this. The methods used to do this are presented in Section 6.3.2. To demonstrate how a biokinetic model can be incorporated in the adapted method-of-moments technique, it is assumed that the individual rates are first-order. The first order rate constant of the rate at which component ' ' is transformed in process '*l'* is denoted $k_{i,l}$. A matrix is used to present these rates. This matrix

relates the transformation of a specific component in a specific process in the same way that the component transformation rate matrix (Table 5.1) does, but only includes the rate constant, not the full rate law. This means that in row 3, column 5, the first-order rate constant for the rate at which component 3 is transformed in process 5 is stated. As the kinetic model being used in this technique is the CWM1, the matrix has 16 rows and 17 columns, for the 16 components and seventeen processes. This matrix is defined as the first-order rate constant matrix and can be found in Table 5.1.

***Table 5.1**: First-order rate constant matrix for the CWM1 components and processes*

The concentration of a component at the outlet of a reactor is dependent on the rate at which that component is consumed or produced, and rate laws are used to quantify this. The batch reactor design equation presented in Section 4.2 shows how the outlet concentration of a component is transformed if the rate law that governs its transformation is first order. In this case the first-order rate constant is in the exponent, as is displayed in Equation 5.2 and has been made bold to highlight its position. To incorporate the multi-component, multi-process biokinetic model, the first-order rate constant is replaced with the first-order rate constant matrix, '*A*'. The matrix has been made bold in Equation 5.3 to show that it is in the same position as the first-order rate constant, '*k'* in Equation 5.2. To ensure that all the rates at which a specific component is transformed in each of the processes is accounted for, two summation terms are used. The first summation term is for the components and ensures that rate constants are used from the correct row and the second summation term is for the processes and ensures that all of the processes are accounted for in the rate of transformation. In Equation 5.3 the design equation, which includes the first-order rate law matrix and summation terms, is presented. There are a total of 'm' components and 'p' processes. In the case of CWM1 $m = 16$ and $p = 17$. The contribution of each process to the degradation or production of a specific component can be summed along the row of that component.

$$C_{out} = C_{in} e^{-\boldsymbol{k}t} \tag{5.2}$$

$$C_{out,i} = \sum_{i=1}^{m} C_{in,i}\, e^{-\sum_{l=1}^{p} \boldsymbol{A}_{i,l}\, t} \tag{5.3}$$

An example of how Equation 5.3 can be used is presented in Equation 5.4 to Equation 5.6. For a system with 5 components and 3 processes, $m = 3$ and $p = 4$. From these equations it can be seen that all the processes in which a specific component is transformed, is accounted for in the overall transformation of the component.

$$C_{out,1} = C_{in,1}\, e^{-\sum_{l=1}^{4} \boldsymbol{A}_{\mathbf{1},l}\, t} = C_{in,1} e^{-\left(k_{1,1} + k_{1,2} + k_{1,3} + k_{1,4}\right) * t} \tag{5.4}$$

$$C_{out,2} = C_{in,2}\, e^{-\sum_{l=1}^{4} \boldsymbol{A}_{\mathbf{2},l}\, t} = C_{in,2} e^{-\left(k_{2,1} + k_{2,2} + k_{2,3} + k_{2,4}\right) * t} \tag{5.5}$$

$$C_{out,3} = C_{in,3}\, e^{-\sum_{l=1}^{4} \boldsymbol{A}_{\mathbf{3},l}\, t} = C_{in,3} e^{-\left(k_{3,1} + k_{3,2} + k_{3,3} + k_{3,4}\right) * t} \tag{5.6}$$

The final step in the adapted method-of-moments technique is to combine the concept of multiple time portions, presented in Section 4.2, with the concept of multiple processes and multiple components being modelled, presented in Equation 5.3. By combining the two parts, both the hydraulic modelling and the kinetic modelling are part of the same equation. This is presented in Equation 5.7.

$$C_{out} = \sum_{i=1}^{m} \sum_{j=1}^{n} \gamma_j C_{in,i} e^{\sum_{l=1}^{p} A_{i,l} t_j} \tag{5.7}$$

An example of how Equation 5.7 can be used is presented in Equation 5.8 to Equation 5.10. This example is for three components ($m = 3$), four processes ($p = 4$) and a residence time distribution curve which is broken into 3 portions ($j = 3$).

$$\begin{aligned} C_{out,1} &= C_{in,1} \sum_{j=1}^{n} e^{-\sum_{l=1}^{4} \boldsymbol{A_{1,l}}\, t_j} \\ &= C_{in,1}\Big(e^{-(k_{1,1}+\, k_{1,2}+k_{1,3}+k_{1,4})*t_1} \\ &\quad + e^{-(k_{1,1}+\, k_{1,2}+k_{1,3}+k_{1,4})*t_2} \\ &\quad + e^{-(k_{1,1}+\, k_{1,2}+k_{1,3}+k_{1,4})*t_3}\Big) \end{aligned} \tag{5.8}$$

$$\begin{aligned} C_{out,2} &= C_{in,2} \sum_{j=1}^{n} e^{-\sum_{l=1}^{4} \boldsymbol{A_{2,l}}\, t_j} \\ &= C_{in,2}\Big(e^{-(k_{2,1}+\, k_{2,2}+k_{2,3}+k_{2,4})*t_1} \\ &\quad + e^{-(k_{2,1}+\, k_{2,2}+k_{2,3}+k_{2,4})*t_2} \\ &\quad + e^{-(k_{2,1}+\, k_{2,2}+k_{2,3}+k_{2,4})*t_3}\Big) \end{aligned} \tag{5.9}$$

$$\begin{aligned} C_{out,3} &= C_{in,3} \sum_{j=1}^{n} e^{-\sum_{l=1}^{4} \boldsymbol{A_{3,l}}\, t_j} \\ &= C_{in,3}\Big(e^{-(k_{3,1}+\, k_{3,2}+k_{3,3}+k_{3,4})*t_1} \\ &\quad + e^{-(k_{3,1}+\, k_{3,2}+k_{3,3}+k_{3,4})*t_2} \end{aligned}$$

$$+e^{-(k_{3,1}+\,k_{3,2}+k_{3,3}+k_{3,4})*t_3}\Big) \tag{5.10}$$

In Section 7.2 the validation of this technique is presented.

5.3 The curve-shift technique with CWM1

The curve-shift technique presented in the previous chapter, Section 4.3, is based on the advective-dispersive transport equation. This solute transport model, in its original form, has been used to model the flow through CWs by many researchers, as was described in Section 2.8.4. The partial differential equation is usually combined with some form of the kinetic model, as was done in BIO_PORE and the HYDRUS Wetland Module, both of which used the CWM1 as the biokinetic model (Meyer *et al.*, 2015). The CWM1 matrices are set up as partial differential equations which are solved along with the advective-dispersive transport equation to describe the transport and degradation of the specific contaminants along the length of the wetland and with respect to time. The data from the curve-shift technique can be used in the same way as the original advective-dispersive transport equation. Owing to the presence of multiple partial differential equations, many of which contain multiple terms, this method requires extensive computing power and is more often used for research purposes, rather than design purposes (Meyer *et al.*, 2015).

5.4: Conclusion

For the two residence time distributions techniques which have been presented to be effective in the modelling of CW degradation processes, they need to be combined with kinetic modelling. This is the case for any reactive system. This chapter shows how this is possible for two presented techniques. For the adapted method-of-moments technique, linear reaction rates are required, which is a limitation on the model but does not disqualify it from use. The curve shift technique can be used in the same way that the original advective-dispersive transport equation has been used by other researchers in the modelling of CWs. In the case of the adapted method-of-moments technique, it is still limited by the assumption of first-order rate laws. In the case of the curve-shift technique, the limitation is the need to solve multiple differential equations which requires large amounts of computing power.

Chapter 6: Linearisation of the kinetic rate laws

6.1: Introduction

For the CWM1 biokinetic model to be combined with the adapted method-of-moments technique, the rate at which an individual component is degraded or produced in a specific process needs to be linearised, and in the form of a first-order rate law. Multiple methods were applied to achieve this. Many of the rate laws in CWM1 are governed by Monod kinetics, which can be either first-order or zero-order, depending on concentration. Due to this, it was initially assumed that the conversion of the rates in CWM1 to first order would be possible. The methods used to do this are described in this chapter.

6.2: Linearisation techniques applied to the kinetic rate laws

6.2.1 Taylor Series Approximation

Taylor series approximation can be used to estimate what a function will look like around a specific point. It makes use of the nth derivatives of the function and adds them at a point (Chiprout and Nakhla, 1994). The mathematical definition of the Taylor Series is presented in Equation 6.1 (Bi, 2018).

$$f(x) \approx G(x) = \sum_{n=0}^{\infty} \frac{f^{(n)}}{n!}(x-a)^n = f(a) + \frac{f'(a)}{1!}(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \frac{f^{(3)}(a)}{3!}(x-a)^3 + \frac{f^{(4)}(a)}{4!}(x-a)^4 \ldots \quad (6.1)$$

A special case of the Taylor Series is the McLaurin series which finds the Taylor series of a function around the point $a = 0$. This is given in Equation 6.2 (Bi, 2018).

$$f(x) \approx G(x) = \sum_{n=0}^{\infty} \frac{f^{(n)}}{n!}(x)^n = f(a) + \frac{f'(0)}{1!}(x) + \frac{f''(0)}{2!}(x)^2 + \frac{f^{(3)}(0)}{3!}(x)^3 + \frac{f^{(4)}(0)}{4!}(x)^4 \ldots \quad (6.2)$$

6.2.2 Padé Approximations

A Padé approximant is an approximation of an expression by a rational function of a specified order between zero and infinity (Chiprout and Nakhla, 1994). Padé approximations represent a function f(x) according to Equation 6.3.

$$f(x) = R_N(x) = \frac{\sum_{j=0}^{m} a_j x^i}{1+\sum_{k=0}^{n} b_k x^k} = \frac{a_0+a_1x+a_2x^2+\ldots+a_mx^m}{b_0+b_1x+b_2x^2+\ldots+b_nx^n} \quad (6.3)$$

Where b_0 is always scaled to 1 and N is defined according to Equation 6.4, the number of unknowns is N+1 and $n \geq 1$ and $m \geq 1$.

$$N = n + m \quad (6.4)$$

This approximation technique was one of the methods that were tried to linearise the reaction rates of CWM1.

To determine the coefficients of x, Equation 6.5 is applied, where p_i are the coefficients from the Taylor expansion.

$$f(x) - R_N(x) = p_0 + p_1x + p_2x^2+\ldots+c_Nx^N - \frac{a_0 + a_1x + a_2x^2+\ldots+a_mx^m}{b_0 + b_1x + b_2x^2+\ldots+b_nx^n}$$

$$= \frac{(p_0+p_1x+p_2x^2+\ldots+c_Nx^N)(b_0+b_1x+b_2x^2+\ldots+b_nx^n)-(a_0+a_1x+a_2x^2+\ldots+a_mx^m)}{b_0+b_1x+b_2x^2+\ldots+b_nx^n} \quad (6.5)$$

For $f(0) = R_N(0)$ it implies that

$$p_0 - a_0 = 0 \quad (6.6)$$

For $f(i)(0) = R_N(i)(0), i = 1,2,\ldots,N$ coefficients of powers of x, up to and including x_N, in the numerator must all be zero, as shown below in Table 1. This can be used to determine the coefficients in the Padé approximant.

***Table 6.1**: Coefficients of powers of x in Padé approximants*

Term in Padé approximation	**Coefficient according to Padé approximation**
x	$b_1p_0 + p_1 - a_1 = 0$
x^2	$b_2p_0 + b_1p_1 + p_2 - a_2 = 0$
$\ldots$	
x^{n+m}	$b_mp_{N-m} + b_{m-1}p_{N-m+1}+\ldots+c_N = 0$

6.3: Results of applying the linearisation techniques

6.3.1 Approximation of general forms

The rate at which individual components of the CWM1 are transformed is dependent on multiple processes, and the rates of those processes are dependent on the concentrations of one or more of the other components. This inter-relatedness makes the modelling detailed and accurate but not simple to work with. To aid the linearisation techniques, some assumptions were made. It was assumed that at an instantaneous moment in time, the concentrations of all components remained constant, except the concentration of the component being investigated. Therefore, for that instantaneous moment the rate at which component '*i'* is transformed in process '*l*' is only dependent on the changing concentration of that component and not the other 15 as well. This rate is hereby defined at the 'simplified rate'. An example of how this works is presented in Equation 6.7 to Equation 6.11.

The rate at which the component fermentation products, as acetate, (S_A), is degraded in the anoxic growth of heterotrophic bacteria is given in Equation 6.7. This rate is a function of the concentration fermentation products as acetate, the concentration of fermentable, readily available COD, the concentration of dissolved oxygen, the concentration of ammonium and ammonia nitrogen, the concentration of S_{NO}, and the concentration of dihydrogen-sulphide sulphur. If it was to be assumed that at an instantaneous moment in time (t_s), the concentrations of all other components except fermentation products as acetate were considered to be constant, then Equation 6.7 could be written in the form shown in Equation 6.8.

$$r_{3,5}(S_A, t_s) = \left(-\frac{1}{Y_H}\right) n_g\, \mu_H \left[\frac{S_A(t_s)}{K_{SA}+S_A(t_s)}\right]\left[\frac{S_A(t_s)}{S_F(t_s)+S_A(t_s)}\right]\left[\frac{K_{OH}}{K_{OH}+S_O(t_s)}\right]\left[\frac{S_{NO}(t_s)}{K_{NOH}+S_{NO}(t_s)}\right]\left[\frac{S_{NH}(t_s)}{K_{NHH}+S_{NH}(t_s)}\right]\left[\frac{K_{H2SH}}{K_{H2SH}+S_{H2S^*}(t_s)}\right] X_H(t_s) \tag{6.7}$$

$$r_{3,5}(S_A, t_s) = Q_{3,5}(t_s)\left[\frac{S_A(t_s)}{P_{3,5}(t_s)+S_A(t_s)}\right]\left[\frac{S_A(t_s)}{R_{3,5}(t_s)+S_A(t_s)}\right] \tag{6.8}$$

Where,

$$Q_{3,5}(t_s) = \left(-\frac{1}{Y_H}\right) n_g \mu_H \left[\frac{K_{OH}}{K_{OH}+S_O(t_s)}\right]\left[\frac{S_{NO}(t_s)}{K_{NOH}+S_{NO}(t_s)}\right]\left[\frac{S_{NH}(t_s)}{K_{NHH}+S_{NH}(t_s)}\right]\left[\frac{K_{H2SH}}{K_{H2SH}+S_{H2S^*}(t_s)}\right] X_H(t_s) \tag{6.9}$$

$$P_{3,5}(t_s) = K_{SA} \tag{6.10}$$

$$R_{3,5}(t_s) = S_F(t_s) \tag{6.11}$$

All the concentrations in terms$Q_{3,5}$, $P_{3,5}$ and $R_{3,5}$are constant at time $t = t_s$.

This technique can be applied to each of the rate laws in the rate law matrix and the results are given in Table 6.2. The rate laws contained in this matrix are not all in the same order, nor are they linear, so changes will still have to be made before they can be applied to any proposed model. The definition of $Q_{i,j}$, $P_{i,j}$ and $R_{i,j}$ for $i = 1,2,3\ldots16$ and $j = 1,2,3\ldots17$, according to the technique applied in Equation 6.7 to Equation 6.11 can be found in Appendix C.

17	Lysis of X_{SOB}		$P_{17,2}$			$P_{17,5}$				$P_{17,9}$	$P_{17,10}$						$P_{17,16}$

The simplification of the rate equations to represent an instantaneous rate take a few common forms, which are given below in Equation 6.12 and Equation 6.13. These will be referred to as Form 1 and Form 2 respectively.

$$r_{i,l}(C_i, t_s) = P_{i,l}(t_s)\left[\frac{C_i(t_s)}{Q_{i,l}(t_s)+C_i(t_s)}\right] \tag{6.12}$$

$$r_{i,l}(C_i, t_s) = P_{i,l}(t_s)\left[\frac{C_i(t_s)}{Q_{i,l}(t_s)+C_i(t_s)}\right]\left[\frac{C_i(t_s)}{R_{i,l}(t_s)+C_i(t_s)}\right] \tag{6.13}$$

To apply these rate laws to a proposed model, they need to be in a linear form, which is not yet the case. Linear approximations techniques were applied to achieve this. For this, the McLaurin series as well as the Taylor series around a non-zero point were investigated.

Taylor Series

As the aim is to linearise the rate equations, Taylor series expansion was used to find the approximations for $n = 1$. The process is presented in Equation 6.14 to Equation 6.28. The Taylor expansion, and therefore the McLaurin series, requires the derivatives of the function around a point to determine the coefficients of C_i in the approximated function. The first derivative of Equation 6.12 (the Form 1 rate equation) can be found in Equation 6.14. At the point $a = 0$, Equation 6.14 becomes Equation 6.15.

$$r_{i,l}{}'(a) = \frac{P_{i,l}(t)Q_{i,l}(t)}{\left(Q_{i,l}(t)+a\right)^2} \tag{6.14}$$

$$r_{i,l}{}'(0) = \frac{P_{i,l}(t)}{Q_{i,l}(t)} \tag{6.15}$$

The Taylor series approximation and the McLaurin series approximation for Equation 6.12, for the $n = 1$, are shown in Equation 6.16 and Equation 6.17, respectively.

$$r_{i,l}(C_i, t) = \frac{P_{i,l}(t)a}{Q_{i,l}(t)+a} + \frac{1}{1!}\frac{P_{i,l}(t)Q_{i,l}(t)}{\left(Q_{i,l}(t)+a\right)^2}\,(C_i - a)^1 \tag{6.16}$$

$$r_{i,l}(C_i, t) = 0 + \frac{1}{1!}\frac{Q_{i,l}(t)}{P_{i,l}(t)}\,C_i{}^1 = \frac{Q_{i,l}(t)}{P_{i,l}(t)}\,C_i \tag{6.17}$$

The first derivative of Form 2, Equation 6.13, can be found in Equation 6.18.

$$r_{i,l}{}'(a) = \frac{P_{i,l}(t)a\left(\left(Q_{i,l}(t)+R_{i,l}(t)\right)a+2Q_{i,l}(t)R_{i,l}(t)\right)}{\left(a+Q_{i,l}(t)\right)^2\left(a+R_{i,l}(t)\right)^2} \tag{6.18}$$

At the point $a = 0$, Equation 6.18 is equal to 0 which means that the estimated function around that point would be equal to 0. For this reason, a quadratic approximation of Equation 6.13 was conducted, and the second derivative is also required. This is shown in Equation 6.19.

$$r_{i,l}{}^{(2)}(a) = \left(\frac{P_{i,l}(t)a\left(\left(Q_{i,l}(t)+R_{i,l}(t)\right)a+2\,Q_{i,l}(t\,)R_{i,l}(t)\right)}{\left(a+Q_{i,l}(t)\right)^2\left(a+R_{i,l}(t)\right)^2}\right)'$$

$$= P_{i,l}(t)\frac{b_5a^5+b_4a^4+b_3a^3+b_2a^2+b_1a^1+b_0a^0}{\left[\left(a+Q_{i,l}(t)\right)^2\left(a+R_{i,l}(t)\right)^2\right]^2} \tag{6.19}$$

where the coefficients are defined in Equation 6.20 to Equation 6.25.

$$b_5 = 2\left(Q_{i,l}(t) + R_{i,l}(t)\right) \tag{6.20}$$

$$b_4 = 4\left(Q_{i,l}(t) + R_{i,l}(t)\right)^2 + 2Q_{i,l}(t)\,R_{i,l}(t) - 4\left(Q_{i,l}(t) + R_{i,l}(t)\right) \tag{6.21}$$

$$b_3 = 2\left(Q_{i,l}(t) + R_{i,l}(t)\right)\left(Q_{i,l}(t)^2 + R_{i,l}(t)^2 + 4Q_{i,l}(t)R_{i,l}(t)\right) - 6\left(Q_{i,l}(t) + R_{i,l}(t)\right)^2 - 4Q_{i,l}(t)R_{i,l}(t) \tag{6.22}$$

$$b_2 = 4\left(Q_{i,l}(t) + R_{i,l}(t)\right)\left(Q_{i,l}(t)^2R_{i,l}(t) + R_{i,l}(t)^2Q_{i,l}(t)\right) + 2Q_{i,l}(t)\,R_{i,l}(t)\left(Q_{i,l}(t)^2 + R_{i,l}(t)^2 + 4Q_{i,l}(t)R_{i,l}(t)\right) - 2Q_{i,l}(t)\,R_{i,l}(t)\left(Q_{i,l}(t)^2 + R_{i,l}(t)^2 + 4Q_{i,l}(t)R_{i,l}(t)\right) - 12Q_{i,l}(t)\,R_{i,l}(t)\left(Q_{i,l}(t) + R_{i,l}(t)\right) \tag{6.23}$$

$$b_1 = 2\left(Q_{i,l}(t) + R_{i,l}(t)\right)Q_{i,l}(t)^2R_{i,l}(t)^2 + 4Q_{i,l}(t)R_{i,l}(t)\left(Q_{i,l}(t)^2R_{i,l}(t) + R_{i,l}(t)^2Q_{i,l}(t)\right) - 2\left(Q_{i,l}(t) + R_{i,l}(t)\right)\left(Q_{i,l}(t)^2R_{i,l}(t) + R_{i,l}(t)^2Q_{i,l}(t)\right) - 4Q_{i,l}(t)\,R_{i,l}(t)\left(Q_{i,l}(t)^2 + R_{i,l}(t)^2 + 4Q_{i,l}(t)R_{i,l}(t)\right) \tag{6.24}$$

$$b_0 = 2Q_{i,l}(t)^3R_{i,l}(t)^3 + 4Q_{i,l}(t)\,R_{i,l}(t)\left(Q_{i,l}(t)^2R_{i,l}(t) + R_{i,l}(t)^2Q_{i,l}(t)\right) \tag{6.25}$$

At the point $a = 0$, Equation 6.19 becomes Equation 6.26.

$$r_{i,l}{}^{(2)}(0) = \frac{Q_{i,l}(t)\left[2Q_{i,l}(t)^3R_{i,l}(t)^3+4Q_{i,l}(t)\,R_{i,l}(t)\left(Q_{i,l}(t)^2R_{i,l}(t)+R_{i,l}(t)^2Q_{i,l}(t)\right)\right]}{Q_{i,l}(t)^4R_{i,l}(t)^4} \tag{6.26}$$

The Taylor series approximation and the McLaurin series approximation for Equation 6.13 for the power of 1 is shown in Equation 6.27 and Equation 6.28, respectively.

$$P_{i,l}(t) = \frac{a^2}{\left(Q_{i,l}(t)+a\right)\left(R_{i,l}(t)+a\right)} + \frac{P_{i,l}(t)a\left(\left(Q_{i,l}(t)+R_{i,l}(t)\right)a+2\,Q_{i,l}(t\,)R_{i,l}(t)\right)}{\left(a+Q_{i,l}(t)\right)^2\left(a+R_{i,l}(t)\right)^2}(C_i - a) + P_{i,l}(t)\frac{b_5a^5+b_4a^4+b_3a^3+b_2a^2+b_1a^1+b_0a^0}{\left[\left(a+Q_{i,l}(t)\right)^2\left(a+R_{i,l}(t)\right)^2\right]^2}(C_i - a)^2 \tag{6.27}$$

$$r_{i,l}(C_i,t) = 0 + 0 + \frac{1}{2!}\frac{Q_{i,l}(t)\left[2Q_{i,l}(t)^3R_{i,l}(t)^3+4Q_{i,l}(t)\,R_{i,l}(t)\left(Q_{i,l}(t)^2R_{i,l}(t)+R_{i,l}(t)^2Q_{i,l}(t)\right)\right]}{P_{i,l}(t)^4R_{i,l}(t)^4}C_i{}^2$$

$$= \frac{P_{i,l}(t)\left[2Q_{i,l}(t)^3R_{i,l}(t)^3+4Q_{i,l}(t)\,R_{i,l}(t)\left(Q_{i,l}(t)^2R_{i,l}(t)+R_{i,l}(t)^2Q_{i,l}(t)\right)\right]}{2\,Q_{i,l}(t)^4R_{i,l}(t)^4}\,C_i{}^2 \tag{6.28}$$

Padé Approximations

Because the aim is to linearise the reaction rates, N=1 for the Padé approximations. This means that $m = 1$ and $n = 0$. Because of this, Equation 5 takes on the form given in Equation 6.29.

$$f(x) - R^1 = \frac{(p_0+p_1x)(1)-(a_0+a_1x)}{1} \tag{6.29}$$

Therefore

$$p_1 - a_1 = 0 \tag{30}$$

This means that the coefficients of the Padé approximant are equal to the coefficients of the Taylor series in the case of a linear equation. For this reason, Padé approximations were not investigated further.

6.3.2 Approximation of Specific Rates

To determine whether the linearisation techniques could be used to model the component transformation rates, a comparison was done between the rate modelled by CWM1, the rate approximated by the McLaurin series, and the rate approximated by the Taylor series at a point. For each component, the comparison of the three was done over a concentration range appropriate to that components, as determined by literature. A basis concentration for each component was also selected. This basis concentration was defined as the point around which the Taylor series approximation was calculated and the point of comparison for the three techniques. The basis concentration for each component was based on values used by another study which used CWM1 for process simulation (Llorens *et al.*, 2011). The basis concentration used for the sixteen components is presented in Table 6.3.

A negative rate indicates that component *i* is being degraded in process *l*, while a positive rate indicates that the component is being produced in the process. Chemical compositions are discussed separately, where necessary.

***Table 6.3**: Basis concentrations used for each of the components in the CWM1 model, the CWM1 modelled rates and the approximation techniques*

Component	Unit	Basis concentration	Reference
Dissolved oxygen	mg O_2/L	0.86	(Llorens *et al.*, 2011)
Fermentable, readily biodegradable soluble COD.	mg COD/L	170	(Llorens *et al.*, 2011)
Fermentation products as acetate	mg COD/L	27	(Llorens *et al.*, 2011)
Inert soluble COD	mg COD/L	13	(Llorens *et al.*, 2011)
Ammonium and ammonia nitrogen	mg N/L	57	(Llorens *et al.*, 2011)
Nitrate and nitrite nitrogen	mg N/L	50.4	(Llorens, Saaltink and García, 2011)
Sulphate sulphur	mg S/L	34	(Llorens *et al.*, 2011)
Dihydrogen-sulphide sulphur.	mg S/L	35	(Llorens, Saaltink and García, 2011)
Slowly biodegradable particulate COD	mg O_2/L	33	(Llorens *et al.*, 2011)
Inert particulate COD	mg O_2/L	13	(Llorens *et al.*, 2011)
Heterotrophic bacteria	mg COD_{BM}/L	100	(Llorens *et al.*, 2011)
Autotrophic nitrifying bacteria	mg COD_{BM}/L	100	(Llorens *et al.*, 2011)
Fermenting bacteria	mg COD_{BM}/L	100	(Llorens *et al.*, 2011)
Acetotrophic methanogenic bacteria	mg COD_{BM}/L	1000	(Llorens *et al.*, 2011)
Acetotrophic sulphate reducing bacteria	mg COD_{BM}/L	340	(Llorens *et al.*, 2011)
Sulphide oxidising bacteria	mg COD_{BM}/L	210	(Llorens *et al.*, 2011)

Linearisation of the rate at which dissolved oxygen is transformed.

The rate at which dissolved oxygen (S_O) is consumed is dependent on four processes in the CWM1 model. All four of these processes take on the form given in Equation 6.12 when simplified according to the method presented in Equation 6.7 to Equation 6.11. The basis concentration that was used for dissolved oxygen was 0.86 mg O_2/L and the range in which the degradation of dissolved oxygen was modelled was 0 mg O_2/L to 1.29 mg O_2/L.

Transformation of oxygen through the aerobic growth of heterotrophic bacteria on fermentable, readily available COD

In Figure 6.1, a comparison of the relationship between the concentration of dissolved oxygen and the rate at which it is transformed during the aerobic growth of heterotrophic bacteria on fermentable, readily available COD, as predicted by the CWM1, the McLaurin series approximation, and Taylor series approximation around the point 0.86 mg O_2/L, is presented. The CWM1 modelled rate predicted that as concentration of dissolved oxygen increases the rate at which it was consumed in this process increases, but the correlation is not linear. The McLaurin series approximation deviated from the CWM1 modelled rate from a concentration of approximately 0.01720 mg O_2/L. At the basis concentration (0.86 mg O_2/L), the rate determined using the McLaurin series approximation is 5.3 times greater than the rate determined using CWM1. The Taylor series approximation was closer in magnitude to the CWM1 modelled rate, than the McLaurin series approximation. A point at which the Taylor series approximation was furthest from the CWM1 modelled rate was at a concentration of 0 mg O_2/L, within the modelled range. In the range of 0.43 mg O_2/L to 1.30 mg O_2/L, the CWM1 modelled rate flattened out, and the root-mean-square error between the CWM1 modelled rate and the Taylor series approximation was 142 mg O_2/L.d, which is 0.9% of the CWM1 modelled rate in that range. From this analysis it was determined that neither the McLaurin series approximation, nor the Taylor series approximation around the basis concentration was a good estimation of the rate at which oxygen is consumed during the aerobic growth of heterotrophic bacteria on fermentable, readily available COD.

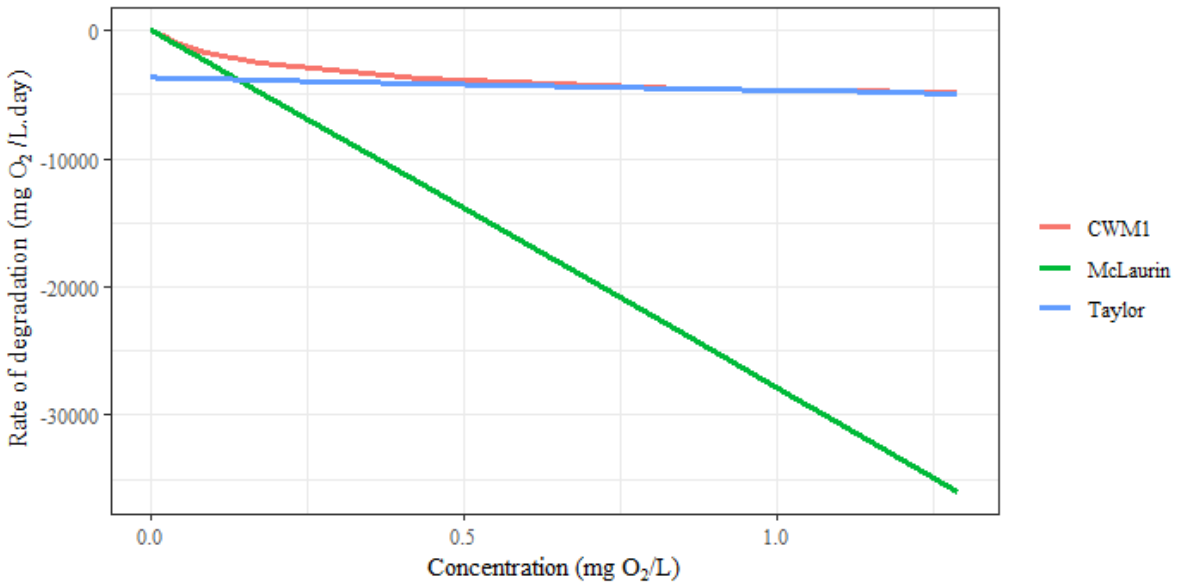

***Figure 6.1**: Comparison of the relationship between the concentration of dissolved oxygen and the rate at which it is transformed during the aerobic growth of heterotrophic bacteria on fermentable, readily available COD, as predicted by the CWM1, the McLaurin series approximation and Taylor series approximation around the point 0.86 mg O_2/L*

Transformation of dissolved oxygen in other processes

The relationship between the concentration of dissolved oxygen and the rate at which it is degraded in the three other concentration-dependent processes (the anoxic growth of heterotrophic bacteria on fermentable, readily available COD, the growth of autotrophic nitrifying bacteria on ammonium and ammonia nitrogen, and the aerobic growth of sulphide oxidising bacteria on dihydrogen-sulphide), is very similar to that of the degradation of aerobic growth of heterotrophic bacteria on fermentable, readily available COD. When linearisation techniques were applied to these processes the same behaviour was found and therefore the same conclusion was made. The magnitude of difference between the McLaurin series approximation and the CWM1 modelled rate at the basis concentration for the three other processes is given in Table 6.4. This is done to give some context to the other results. The full results can be found in Appendix D.

Linearisation of the rate at which fermentable, readily biodegradable COD, is transformed.

The rate at which fermentable, readily biodegradable COD (hereafter referred to as COD) (S_F) is consumed is dependent on ten processes in the CWM1 model. Seven of the ten processes are not dependent on the concentration of COD and so do not need to be linearised. In their

simplified form, two of the processes take on the form given in Equation 6.12 and one takes on the form given in Equation 6.13. The basis concentration of COD used in the model is 170 mg COD/L and the range in which the processes were modelled is 0 mg COD/L to 220 mg COD/L.

Transformation of fermentable, readily biodegradable COD through the erobic growth of heterotrophic bacteria on fermentable, readily biodegradable COD

In Figure 6.2, a comparison of the relationship between the concentration of COD and the rate at which it is transformed during the aerobic growth of heterotrophic bacteria on fermentable, readily available COD, as predicted by the CWM1, the McLaurin series approximation and Taylor series approximation around the point 170 mg COD/L, is presented. The y-axis on the left-hand side gives the rate determined using the CWM1 model and the Taylor series approximation, while the y-axis on the right-hand side gives the rate determined using the McLaurin series approximation. The rate determined using the McLaurin series approximation was several orders of magnitudes greater than the rates determined using the CWM1 model and Taylor series approximation and is shown on a separate axis so that the trend of all three responses can be seen clearly.

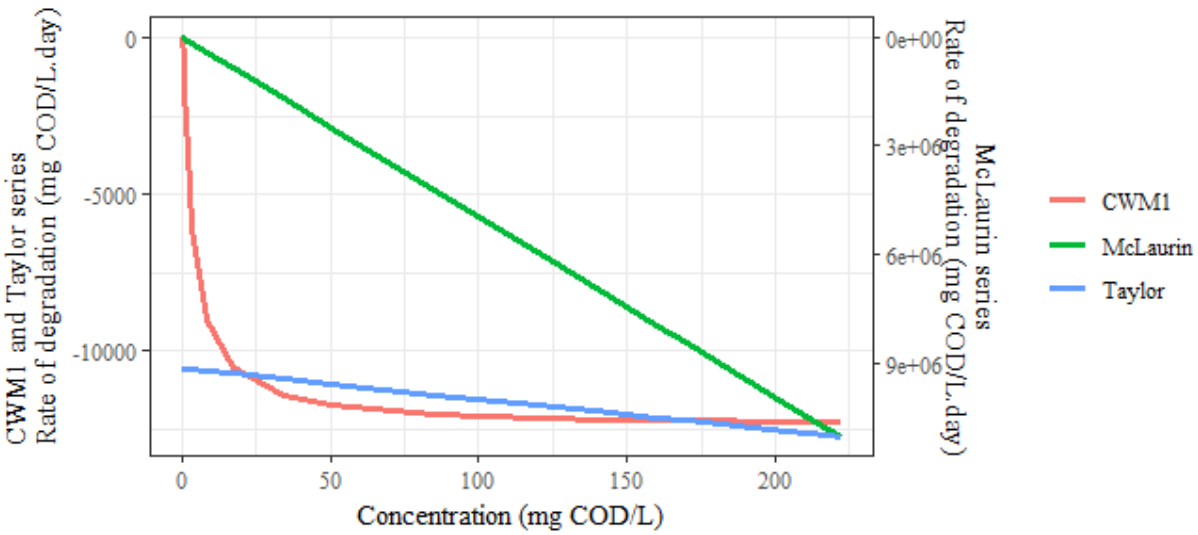

***Figure 6.2**: Comparison of the relationship between the concentration of COD and the rate at which it is transformed during the aerobic growth of heterotrophic bacteria on fermentable, readily available COD, as predicted by the CWM1, the McLaurin series approximation and Taylor series approximation around the point 170 mg COD/L*

All three modelled rates predicted that the higher the concentration of COD, the faster it was degraded in the process. The CWM1 model predicted that the rate of transformation was

dependent on the concentration of COD for the lower concentrations but at approximately 150 mg COD/L the rate was no longer concentration dependent. The CWM1 modelled rate is based on Monod kinetics and therefore this behaviour is not unexpected. The reason for the flattening out of the curve could be because at around this concentration the bacteria are saturated and cannot transform the COD any faster.

The rate predicted by the Taylor series approximation was in the same order of magnitude as the CWM1 modelled rate but did not display the same behaviour around the basis concentration. In the range between 17 mg COD/L and 222 mg COD/L the root-mean-square error between the CWM1 modelled rate and the Taylor series approximation was 410 mg COD/L.d, which is 3.4% of the CWM1 modelled rate. However, when concentrations lower than 17 mg COD/L were included, the error became 5130 mg COD/L.d, which was 60.7% of the mean rate between 0 mg COD/L and 222 mg COD/L. The concentration of COD is likely to fall below 17 mg COD/L and because of this, there is a range in which the Taylor series approximation deviates to a significant extent from the CWM1 modelled rate. From this information, it can be determined that the Taylor series approximation is not a good linear estimate of the rate. A comparison of the McLaurin series predicted rate and the CWM1 modelled rate showed that not only was the trend of the rates different, but they were also magnitudes apart. At the basis concentration, the McLaurin approximation was 692 times greater than the CWM1 modelled data. This difference in magnitude means that the McLaurin series approximation is not a good estimation of the CWM1 modelled rate.

Transformation of fermentable, readily available COD in other processes

A similar type of behaviour was seen for the approximations of the transformation of COD in the aerobic growth of heterotrophic bacteria on fermentation products, as acetate (S_A). The CWM1 modelled rate equation was of the same form and the approximations displayed the same deviations. The factor by which the McLaurin series approximation was out for each of the processes can be found in Table 6.4. Figures comparing the CWM1 modelled rate, and the approximations can be found in Appendix D.

Linearisation of the rate at which fermentation products as acetate, is transformed.

The rate at which fermentation products, as acetate, (hereafter referred to as acetate) (S_A), is transformed is dependent on five processes, according to the CWM1 model. Acetate is transformed through the anoxic growth of heterotrophic bacteria on COD and acetate, and the growth of fermenting bacteria, acetotrophic, methanogenic bacteria and acetotrophic, sulphate reducing bacteria. The growth of acetotrophic, sulphate reducing bacteria is not dependent on the concentration of acetate and so linearisation techniques were not applied to this rate. Two of the other rates take the form of Equation 6.12 and two take the form of Equation 6.13. The basis concentration for acetate in this model is 27 mg COD/L and the range over which the linearisation techniques were applied is 0 mg COD/L to 40 mg COD/L.

Transformation of acetate through the anoxic growth of heterotrophic bacteria on COD

In Figure 6.3 a comparison of the relationship between the concentration of acetate and the rate at which it is transformed during the anoxic growth of heterotrophic bacteria on COD, as predicted by the CWM1, the McLaurin series approximation, and Taylor series approximation around the point 27 mg COD/L, is presented. The y-axis on the left-hand side gives the rate determined using the CWM1 model and the McLaurin series approximation, while the y-axis on the right-hand side gives the rate determined using the Taylor series approximation. The rate determined using Taylor series approximation was several orders of magnitudes greater than the rates determined using the CWM1 model and McLaurin series approximation and is shown on a separate axis so that the trend of all three responses can be seen clearly. The Taylor series approximation was so much greater in magnitude because of one of the original rate constants used in CWM1 was very large and had a dominating effect on the gradient of the response.

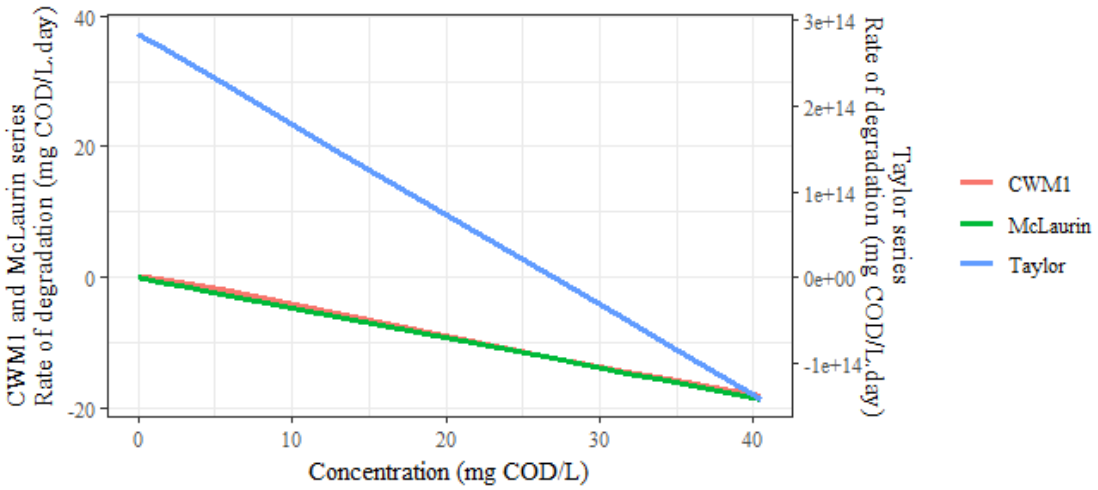

***Figure 6.3**: Comparison of the relationship between the concentration of acetate and the rate at which it is transformed during the anoxic growth of heterotrophic bacteria on COD, as predicted by the CWM1, the McLaurin series approximation and Taylor series approximation around the point 27 mg COD/L*

All three predictions showed that the higher the concentration of acetate, the higher the rate at which it was transformed in the anoxic growth of heterotrophic bacteria on COD. Within the modelled concentration range, the relationship between acetate concentration and the rate at which it is transformed in this process, as predicted by the CWM1 model, was linear. The McLaurin series is a good approximation of the CWM1 modelled rate, with a root-mean-square error of 0.3 mg COD/L.d, which is 3.3% of the average rate, within the modelled concentration range. From this information, it can be said that the McLaurin series approximation can be used to linearise the rate at which acetate is degraded in the anoxic growth of heterotrophic bacteria on COD.

The Taylor series approximation also predicted a linear relationship between the concentration of acetate and the rate at which it was transformed. However, the magnitude of Taylor series approximation was much greater than the CWM1 modelled. The Taylor series approximation also predicts a production of acetate above the basis concentration. The exponents calculated for the Taylor series approximation were very high and so the gradient of the approximation was much steeper than the CWM1 modelled rate.

Transformation of fermentation products, as acetate, in the anoxic growth of heterotrophic bacteria on acetate

The rate at which acetate is transformed in the anoxic growth of heterotrophic bacteria on acetate displayed the same behaviour as the anoxic growth of the bacteria on COD and the

same conclusions about the approximations can be drawn. The root-mean-square error of the McLaurin series approximation for the rate at which acetate is degraded in the anoxic growth of heterotrophic bacteria on acetate was 0.363 mg COD/L.d, which is 3.6% of the average rate, within the modelled concentration range, and the figures which display the comparisons of the approximations as well as the CWM1 modelled rate can be found in Appendix D.

Transformation of acetate in the growth of acetotrophic methanogenic bacteria

In Figure 6.4, a comparison of the relationship between the concentration of acetate and the rate at which it is transformed during the growth of acetotrophic methanogenic bacteria, as predicted by the CWM1, the McLaurin series approximation and Taylor series approximation around the point 27 mg O_2/L, is presented. All three models predicted that as the concentration of acetate increased, the rate at which it was transformed through the growth of acetotrophic methanogenic bacteria increased. The rate of transformation predicted by the CWM1 was not linear.

The higher the concentration of acetate, the greater the deviation of the McLaurin series approximation from the CWM1 modelled rate and at the basis concentration the McLaurin series approximation is 1.48 times higher than the CWM1 modelled rate. The Taylor series approximation around the basis concentration is similar to the CWM1 modelled rate but overestimates the rate of degradation at concentrations higher and lower than the basis concentration. Neither the McLaurin series nor the Taylor series approximation gives an accurate representation of the CWM1 modelled rate.

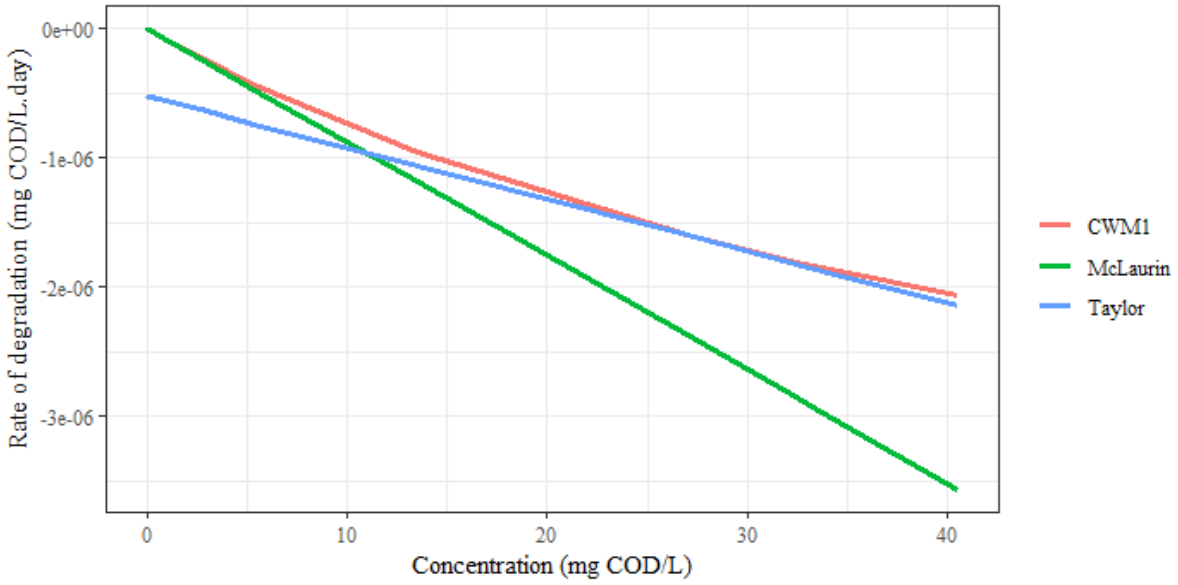

***Figure 6.4**: Comparison of the relationship between the concentration of acetate and the rate at which it is transformed during the growth of acetotrophic methanogenic bacteria, as predicted by the CWM1, the McLaurin series approximation and Taylor series approximation around the point 27 mg O_2/L*

Transformation of fermentation products as acetate in the growth of acetotrophic, sulphate reducing bacteria.

The rate at which acetate is degraded in the growth of acetotrophic, sulphate reducing bacteria had the same behaviour as was described for rate of transformation through the growth of acetotrophic, methanogenic bacteria and the same conclusions about the approximations can be drawn. The factor by which the McLaurin series approximation was out for each of the processes can be found in Table 6.4. Figures comparing the CWM1 modelled rate, and the approximations can be found in Appendix D.

Linearisation of the rate at which ammonium and ammonia nitrogen is transformed.

The rate at which ammonia and ammonium nitrogen (hereafter referred to as ammonium) (S_{NH}) is transformed, is dependent on seventeen processes. Ammonium is degraded in the process of nitrification and the growth of biomass and is produced in the degradation of organic matter and the lysis of biomass. Seven of these seventeen processes are not based on the concentration of ammonium and do not need to be linearised. The other ten processes all take on the form given in Equation 6.12. The basis concentration of ammonium is 57 mg N/L and the range across which the approximations were calculated was 0 mg N/L to 82.5 mg N/L.

Transformation of ammonium through the aerobic growth of heterotrophic bacteria on COD.

In Figure 6.5 a comparison of the relationship between the concentration of ammonium and the rate at which it is transformed during the aerobic growth of heterotrophic bacteria on COD, as predicted by the CWM1, the McLaurin series approximation, and Taylor series approximation around the point 57 mg COD/L, is presented. The y-axis on the left-hand side gives the rate determined using the CWM1 model and the Taylor series approximation, while the y-axis on the right-hand side gives the rate determined using the McLaurin series approximation. The rate determined using the McLaurin series approximation was several orders of magnitudes greater than the rates determined using the CWM1 model and Taylor series approximation and is shown on a separate axis so that the trend of all three responses can be seen clearly.

The relationship between the CWM1 modelled rate and the concentration of ammonium was exponential and as the concentration of ammonium increases, the rate at which it is degraded also increases but begins to flatten out at approximately 10 mg N/L. There comes a point at which the process is limited, not by the concentration of ammonium, but by the rate at which bacteria can degrade ammonium and so the relationship between the concentration of ammonium and the rate at which it is degraded in this process becomes close to zero-order.

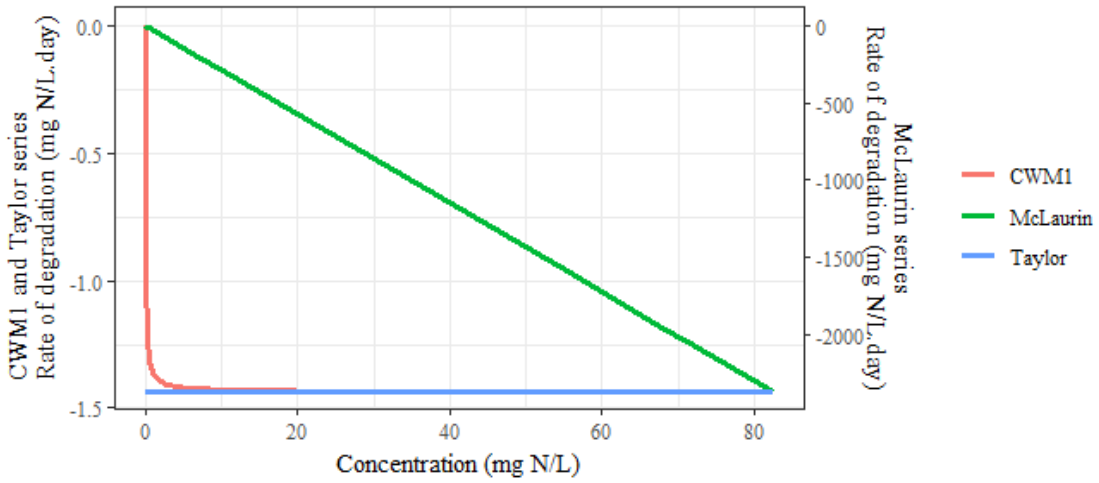

Figure 6.5*: Comparison of the relationship between the concentration of ammonium and the rate at which it is transformed during the aerobic growth of heterotrophic bacteria on COD, as predicted by the CWM1, the McLaurin series approximation and Taylor series approximation around the point 57 mg COD/L*

In Figure 6.5 it can be seen that for the concentration range of 30 mg N/L to 75 mg N/L the Taylor series approximation was very similar to that of the CWM1 modelled rate, with a root mean squared error of 2.93×10^{-4} mg N/L.d, which was 0.02% of the CWM1 modelled rate in that range. However, at concentrations lower than 25 mg N/L, the Taylor series approximation deviated from the CWM1 modelled and was not a good representation of the CWM1 modelled rate. Across the full range modelled, the root mean square error is 0.44 mg N/L.d. At the basis concentration, the McLaurin series approximation rate was 1141 times larger in magnitude than the CWM1 modelled rate. From this it can be stated that the two methods do not give a good enough estimation of the CWM1 modelled rate and linearisation of the rate was not achieved.

Transformation of ammonium and ammonia nitrogen in other processes

The relationship between the concentration of ammonium and the rate at which it is degraded in the six other concentration-dependent processes, is very similar to that of the relationship between the concentration of ammonium and the rate at which it is transformed through the aerobic growth of heterotrophic bacteria on fermentable, readily available COD. The linearisation techniques applied also follow the same behaviours and therefore the same conclusion is made. The magnitude of difference between the McLaurin series approximation and the CWM1 modelled rate at the basis concentration for the six other processes is given in Table 6.4. This is done to give some context to the other results. More details can be found in Appendix D.

Linearisation of the rate at which nitrate and nitrite nitrogen is transformed

The rate at which nitrate and nitrite nitrogen (hereafter referred to as nitrate) (S_{NO}) is degraded and produced is dependent on five processes in the CWM1 model. Nitrate is produced through nitrification and consumed through denitrification and anoxic sulphide oxidation. One of the five processes is not dependent on the concentration of nitrate and so does not need to be linearised in this context. The other four processes all take the form of Equation 6.12. The basis concentration of nitrate is 50.4 mg N/L and the range across which the approximations were compared with the CWM1 modelled is 0 mg N/L to 75.6 mg N/L.

Transformation of nitrate and nitrite nitrogen through the anoxic growth of sulphide oxidising bacteria on dihydrogen-sulphide sulphur

In Figure 6.6 a comparison of the CWM1 modelled rate, the McLaurin series, and the Taylor approximation around the basis concentration (50.4 mg N/L), for the transformation of nitrate through the anoxic growth of sulphide oxidising bacteria on dihydrogen-sulphide sulphur is displayed. The y-axis on the left-hand side gives the rate determined using the CWM1 model and the Taylor series, while the y-axis on the right-hand side gives the rate determined using the McLaurin series. The McLaurin series rate was several orders of magnitudes greater than the CWM1 model and Taylor series rates and has been shown on a separate axis so that the trend of all three responses can be seen clearly.

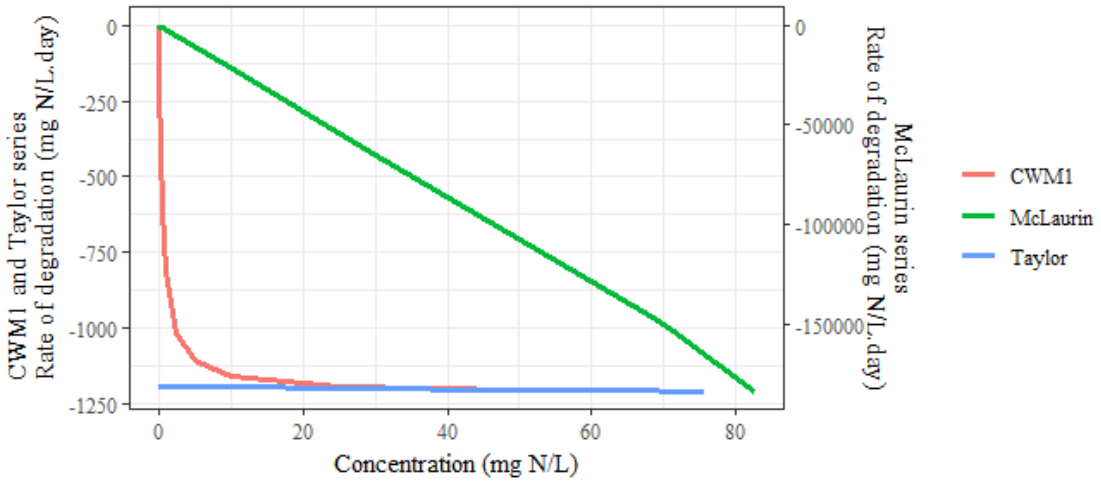

***Figure 6.6**: Comparison of the CWM1 modelled rate, the McLaurin series, and the Taylor approximation around the basis concentration (50.4 mg N/L), for the transformation of nitrate through the anoxic growth of sulphide oxidising bacteria on dihydrogen-sulphide sulphur*

The rate of transformation as predicted by the CWM1 modelled displayed exponential behaviour and flattened out at a relatively low concentration. This happened because the rate at which nitrate is transformed through the anoxic growth of sulphide oxidising bacteria on dihydrogen-sulphide sulphur is not limited by the concentration of nitrate but the rate at which the sulphide oxidising bacteria can transform nitrate. For the Taylor series approximation, it can be seen that in the concentration range of 30 mg N/L to 75 mg N/L the Taylor series approximation is very similar that of the CWM1 modelled rate, with a root mean squared error of 2.76 mg N/L.d, which is 0.23% of the CWM1 modelled rate at that point. However, at a concentration lower than 25 mg N/L, the Taylor series approximation deviates from the CWM1

modelled and is not a good representation of the CWM1 modelled rate. The McLaurin series approximation is a straight line with a much steeper gradient than the flattened-out section of the CWM1 modelled rate. At the basis concentration (50.4 mg N/L), the McLaurin series approximation was 101.8 times greater than the CWM1 modelled rate. From this it can be determined is that the McLaurin series approximation is not an accurate linearisation of the CWM1 modelled rate.

Transformation of nitrate and nitrite nitrogen through other processes

The relationship between the concentration of nitrate and the rate at which it is degraded in the three other concentration-dependent processes (aerobic and anoxic growth of heterotrophic bacteria on acetate and the growth of acetotrophic sulphate reducing bacteria), is very similar to that of the relationship between the substrate and degradation of aerobic growth of sulphide oxidising bacteria on dihydrogen-sulphide sulphur. The linearisation techniques applied also follow the same behaviours and therefore the same conclusion is made. The magnitude of difference between the McLaurin series approximation and the CWM1 modelled rate at the basis concentration for the three other processes is given in Table 6.4. This is done to give some context to the other results. More details can be found in Appendix D.

Linearisation of the rate at which sulphate sulfur is transformed.

The rate at which sulphate sulphur (hereafter referred to as sulphate) (S_{SO4}) is transformed dependent on three processes in the CWM1 model. In aerobic and anoxic sulphide oxidation sulphate is produced but these rates are not dependent on the concentration of the sulphate. Sulphate reducing bacteria use sulphate as an electron acceptor for the oxidation of acetate and is dependent on the concentration of sulphate This rate takes the form of Equation 6.12 in its simplified form. The basis concentration of sulphate is 35 mg S/L and the concentration range across which the approximations were modelled id 0 mg S/L to 52.5 mg S/L.

Transformation of sulphate-sulphur through the growth of acetotrophic, sulphate reducing bacteria.

In Figure 6.7 a comparison of the relationship between the concentration of sulphate and the rate at which it is transformed during the growth of acetotrophic sulphate reducing bacteria, as predicted by the CWM1, the McLaurin series approximation and Taylor series approximation around the point 35 mg O_2/L, is presented. All three models predicted that as the concentration

of sulphate increased, the rate at which it was transformed through the growth of acetotrophic sulphate reducing bacteria increased. The rate of transformation predicted CWM1 was neither linear nor exponential. The Taylor series approximation is only accurate around the basis concentration, but on either side, the Taylor series approximation is greater in magnitude than the CWM1 modelled rate. It can be concluded that this approximation is not a linear estimation of the CWM1 modelled rate. The McLaurin series approximation predicted a linear behaviour but as the concentration of sulphate increased, it deviated further from the CWM1 predicted concentration. At the basis concentration of 35 mg N/L the McLaurin series approximation is 2.84 times greater than the CWM1 modelled rate. This leads to the conclusion the McLaurin series cannot be used for the linear approximation of the degradation of sulphate in the growth of acetotrophic, sulphate reducing bacteria. Given that neither the McLaurin series nor the Taylor series approximation around the basis concentration gives a good linear estimation of the CWM1 modelled rate, it can be said that the rate at which sulphate is degraded cannot be represented in a linear approximation.

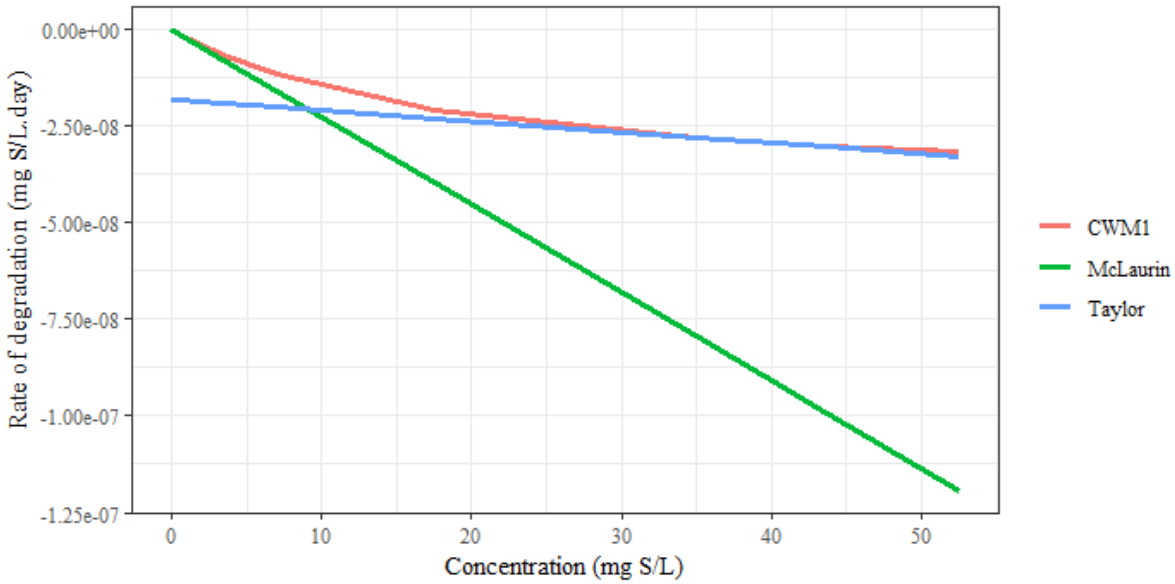

***Figure 6.7**: Comparison of the relationship between the concentration of sulphate and the rate at which it is transformed during the growth of acetotrophic sulphate reducing bacteria, as predicted by the CWM1, the McLaurin series approximation and Taylor series approximation around the point 35 mg O_2/L*

Linearisation of the rate at which dihydrogen-sulphide sulphur is transformed

The rate at which dihydrogen-sulphide sulphur (hereafter referred to us dihydrogen-sulphide) is transformed is dependent on three processes, all of which are dependent on the concentration

of dihydrogen-sulphide sulphur and take the form of Equation 6.12 in their simplified form. Dihydrogen-sulphide sulphur is produced in the growth of acetotrophic, sulphate reducing bacteria and is degraded in the aerobic and anoxic growth of sulphide oxidising bacteria on dihydrogen-sulphide sulphur. The basis concentration of dihydrogen-sulphide sulphur is 34 mg S/L and the concentration range across which the approximations were compared with the CWM1 modelled rate is 0 mg S/L to 51 mg S/L.

Transformation of dihydrogen-sulphide sulphur through the growth of acetotrophic, sulphate reducing bacteria.

In Figure 6.8 a comparison of the relationship between the concentration of dihydrogen-sulphide and the rate at which it is transformed during the growth of acetotrophic sulphate reducing bacteria, as predicted by the CWM1, the McLaurin series approximation and Taylor series approximation around the point 34 mg O_2/L, is presented. As the concentration of dihydrogen-sulphide increased, the rate which it was produced through the growth of acetotrophic sulphate reducing bacteria increased. The Taylor series approximation series was greater than the CWM1 modelled rate for the full concentration range, except at the basis concentration, at which points the rates were equal. As the concentration of dihydrogen-sulphide increased the more the McLaurin series approximation deviated from the CWM1 modelled rate. At the basis concentration, the McLaurin series approximation is 1.25 times greater than the CWM1 modelled rate. Neither the McLaurin series nor the Taylor series approximation is a good estimation of the CWM1 modelled rate.

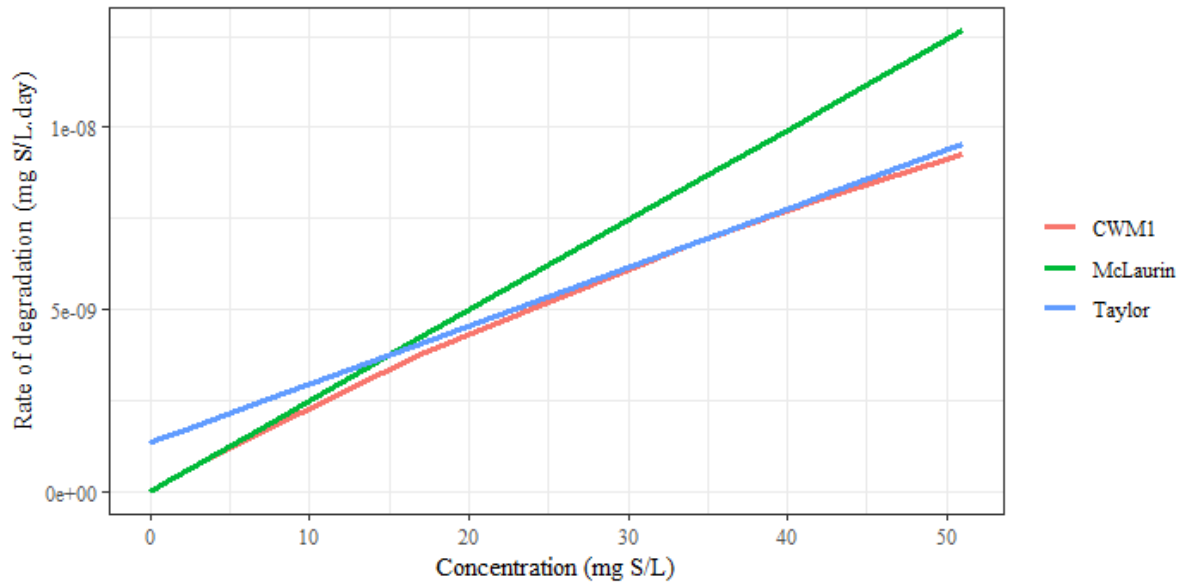

***Figure 6.8**: Comparison of the relationship between the concentration of dihydrogen-sulphide and the rate at which it is transformed during the growth of acetotrophic sulphate reducing bacteria, as predicted by the CWM1, the McLaurin series approximation and Taylor series approximation around the point 34 mg O_2/L*

Transformation of dihydrogen-sulphide sulphate through the aerobic growth of sulphide oxidising bacteria on dihydrogen-sulphide sulphur

In Figure 6.9 a comparison of the relationship between the concentration of dihydrogen-sulphide and the rate at which it is transformed through the aerobic growth of sulphide oxidising bacteria on dihydrogen-sulphide as predicted by the CWM1, the McLaurin series approximation and Taylor series approximation around the point 34 mg O_2/L, is presented. The y-axis on the left-hand side gives the rate determined using the CWM1 model and the Taylor series approximation, while the y-axis on the right-hand side gives the rate determined using the McLaurin series approximation. The rate determined using the McLaurin series approximation was several orders of magnitudes greater than the rates determined using the CWM1 model and Taylor series approximation and is shown on a separate axis so that the trend of all three responses can be seen clearly.

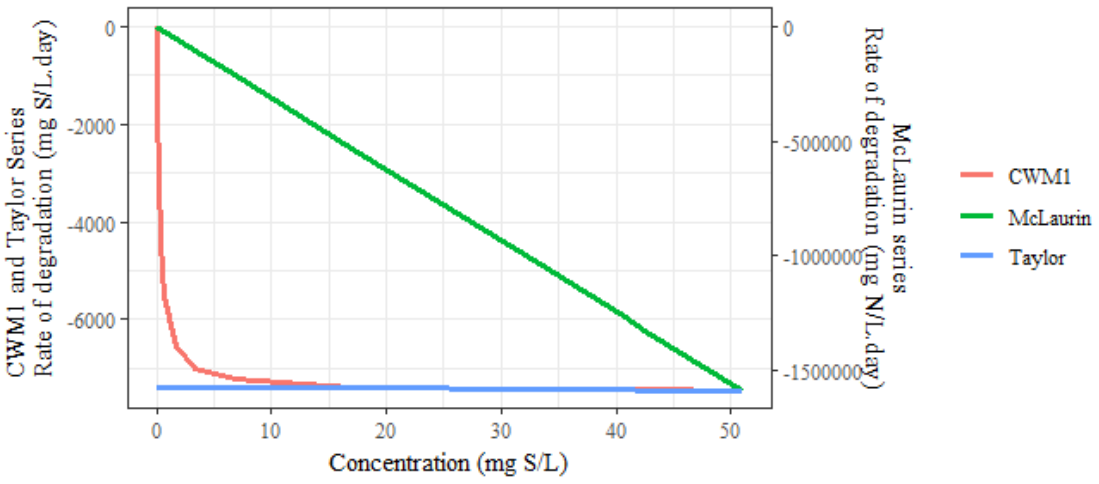

***Figure 6.9**: Comparison of the relationship between the concentration of dihydrogen-sulphide and the rate at which it is transformed through the aerobic growth of sulphide oxidising bacteria on dihydrogen-sulphide as predicted by the CWM1, the McLaurin series approximation and Taylor series approximation around the point 34 mg O_2/L*

The rate predicted by CWM1 modelled was an exponential function, and as the concentration of dihydrogen-sulphide increased, the rate at which it was degraded in this process increased in magnitude, before flattening out at a concentration of approximately10 mg S/L. At that point, the rate of aerobic growth of sulphide oxidising bacteria on dihydrogen-sulphide was not limited by the concentration of dihydrogen-sulphide but rather the rate at which sulphide oxidising bacteria can degrade the dihydrogen-sulphide. In the range of 10 mg S/L and 50 mg S/L the Taylor series approximation was similar to the CWM1 modelled rate and the root mean square error was 66.7 mg S/L.d, which is 0.9% of the CWM1 modelled rate. However, at concentrations lower than 10 mg S/L the error was much larger at 4481 mg S/L.d. From this, it can be said that the Taylor series approximation is not a good estimate of the CWM1 modelled rate. The McLaurin series approximation displayed a linear behaviour and was magnitudes higher than the CWM1 modelled rate. At the basis concentration, (34 mg S/L), the magnitude of the McLaurin series approximation is 143 times greater than the CWM1 modelled rate at the same point. Considering the deviation in the behaviour and the magnitude of the difference at the basis concentration, it can be concluded that the McLaurin series approximation is not an appropriate estimation of the relationship between the concentration of dihydrogen-sulphide sulphur and the rate at which it is degraded in the aerobic growth of sulphide oxidising bacteria on dihydrogen-sulphide sulphur.

Transformation of dihydrogen-sulphide sulphur in other processes

The relationship between the concentration of dihydrogen-sulphide sulphur and the rate at which it is degraded in the anoxic growth of sulphide oxidising bacteria on dihydrogen-sulphide sulphur was very similar to that of the aerobic growth of sulphide oxidising bacteria on dihydrogen-sulphide sulphur. The linearisation techniques applied also follow the same behaviours and therefore the same conclusion is made. The magnitude of difference between the McLaurin series approximation and the CWM1 modelled rate at the basis concentration for the anoxic growth of sulphide oxidising bacteria on dihydrogen-sulphide sulphur is given in Table 6.4. This is done to give some context to the other results. More details can be found in Appendix D.

Linearisation of the rate at which slowly biodegradable particulate COD is transformed

The rate at which slowly biodegradable, particulate COD is degraded and produced is dependent on seven processes. Six of these processes are the lysis of different bacterial groups, in which slowly biodegradable, particulate COD is produced and none of these processes are dependent on the concentration of slowly biodegradable, particulate COD. The one process which is dependent on the concentration of slowly biodegradable, particulate COD is hydrolysis and this rate takes the simplified form given in Equation 6.12. The basis concentration of slowly biodegradable, particulate COD used was 33 mg O_2/L and the concentration range across rate was modelled was 0 mg O_2/L to 49 mg O_2/L.

Transformation of slowly biodegradable particulate COD through hydrolysis

In Figure 6.10 a comparison of the relationship between the concentration of biodegradable, particulate COD, and the rate at which it is transformed through the hydrolysis as predicted by the CWM1, the McLaurin series approximation and Taylor series approximation around the point 33 mg O_2/L, is presented. All three models predicted that as the concentration of biodegradable, particulate COD increased, the rate at which it was transformed through hydrolysis also increased. The CMW1 modelled rate was neither linear nor exponential in the concentration range. From this figure, it can be seen that the McLaurin series deviates from the CWM1 modelled rate at concentrations greater than 0 mg O_2/L. At the basis concentration (33 mg O_2/L) the McLaurin series approximation is 2.65 times greater in magnitude than the CWM1 modelled rate. This deviation indicates that the linear McLaurin series approximation

is not a good estimation of the CWM1 modelled rate. From a comparison of the CWM1 modelled rate and the Taylor series approximation around the basis concentration (33 mg O_2/L) it can be determined that the Taylor series approximation estimates a rate of greater magnitude than the CWM1 modelled rate at every point except the basis concentration. This linear approximation is not a good estimation of the CWM1 modelled rate.

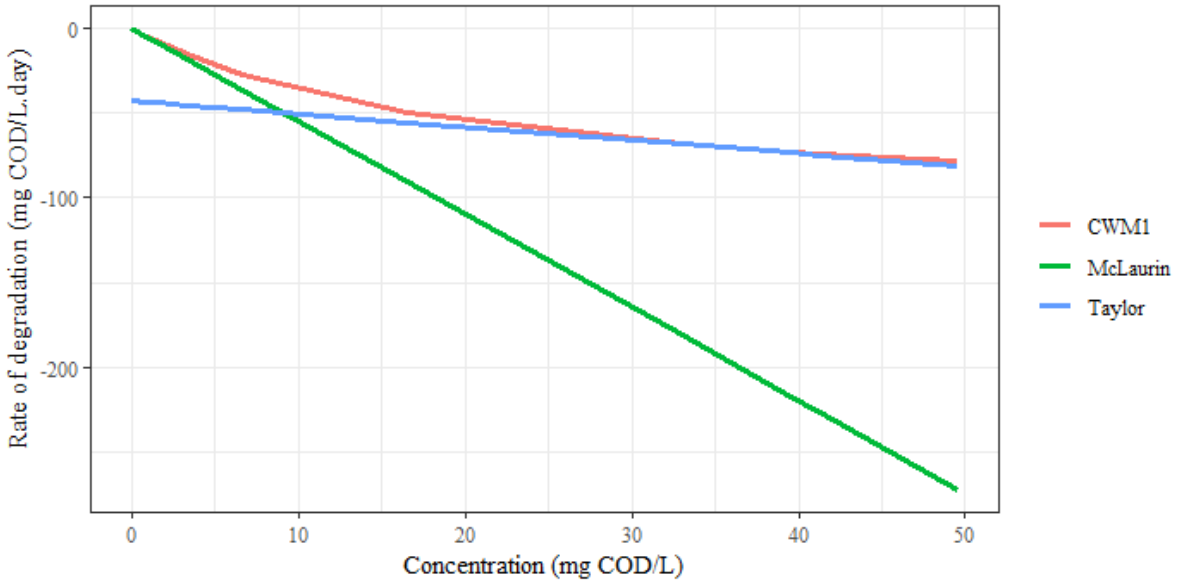

***Figure 6.10**: Comparison of the relationship between the concentration of biodegradable, particulate COD, and the rate at which it is transformed through the hydrolysis as predicted by the CWM1, the McLaurin series approximation and Taylor series approximation around the point 33 mg O_2/L*

The code used and data used to generate Figure 6.1 to Figure 6.10 can be found in Appendix E.

6.3.3 Summary of linear approximation results

In Table 6.4 a comparison of the magnitude of the CWM1 modelled rates and McLaurin series approximation of rates at the basis concentration of each component is given. The Taylor series approximations are not included in this table because the Taylor series approximations were determined around the basis concentration and therefore, at that concentration were equal to the CWM1 modelled rate. The McLaurin series gave similar looking graphs in all cases with the exception of the magnitude of the deviation in all cases given in Table 6.4.

***Table 6.4**: Comparison of the magnitude of the CWM1 modelled rate and the McLaurin series approximation at the basis concentration, for each of the components and processes which are concentration-dependent*

Component	Process	Factor by which the McLaurin series approximation is out when compared to the CWM1 modelled rate, at the basis concentration
Dissolved oxygen	Anoxic growth of heterotrophic bacteria on fermentable, readily biodegradable COD	5.3
	Growth of autotrophic nitrifying bacteria on fermentation products, as acetate	1.86
	Aerobic growth sulphide oxidising bacteria on dihydrogen-sulphur	5.3
Fermentable, readily biodegradable COD	Aerobic growth of heterotrophic bacteria fermentation products, as acetate	692.0
	Growth of fermenting bacteria	7.07
Fermentation products, as acetate	Growth of acetotrophic, sulphate reducing bacteria	2.13
Ammonia and ammonium nitrogen	Aerobic growth of heterotrophic bacteria fermentation products, as acetate	1141
	Anoxic growth of heterotrophic bacteria on fermentable, readily biodegradable COD	1141
	Anoxic growth of heterotrophic bacteria fermentation products, as acetate	1141
	Growth of autotrophic nitrifying bacteria on fermentation products, as acetate	115
	Growth of fermenting bacteria	5701
	Growth of acetotrophic methanogenic bacteria	5701
	Growth of acetotrophic, sulphate reducing bacteria	5701
	Aerobic growth sulphide oxidising bacteria on dihydrogen-sulphur	1141
	Anoxic growth sulphide oxidising bacteria on dihydrogen-sulphur	1141
Nitrate and nitrite nitrogen	Aerobic growth of heterotrophic bacteria fermentation products, as acetate	101.8
	Anoxic growth of heterotrophic bacteria fermentation products, as acetate	101.8
Dihydrogen-sulphide sulphur	Anoxic growth sulphide oxidising bacteria on dihydrogen-sulphur	142.7

Dissolved oxygen

The rate at which dissolved oxygen is removed in CWs is dependent on four processes. For each of these processes, the McLaurin series approximation deviated further from the CWM1 modelled rate as the concentration of dissolved oxygen increased, and therefore the McLaurin series was not used to linearise the reaction rates of dissolved oxygen. The Taylor series approximation was similar in magnitude and gradient to the CWM1 modelled rate but only within a very limited range. The greatest deviation was at low concentrations of dissolved oxygen, and as these concentrations are common in CWs, the Taylor series approximation was not used to linearise the reaction rates of dissolved oxygen.

Fermentable, readily biodegradable COD

The rate of degradation of fermentable, readily available COD in CWs is dependent on three processes. For each of these processes, the McLaurin series approximation deviated further from the CWM1 modelled rate as the concentration of fermentable, readily available COD increased, and therefore the McLaurin series was not used to linearise the reaction rates of fermentable, readily available COD. The Taylor series approximation was within the same magnitude as the CWM1 modelled rate, neither the gradient at the basis concentration nor the type of behaviour displayed were the same. Because of this, the Taylor series will deviate further at higher concentrations and as fermentable, readily available COD is the main COD component (according to CWM1) high concentrations are expected in CWs. This was the case for all three processes and therefore the Taylor series approximation was not used to linearise the reaction rates of fermentable, readily available COD.

Fermentation products, as acetate

The rate of transformation of fermentation products as acetate is dependent on four processes. For two of these processes, the McLaurin series approximation deviated further from the CWM1 modelled as the concentration of fermentation products as acetate increased, and so McLaurin series approximations could not be used for these processes. The Taylor series approximation of the rate at which acetate is transformed in the growth of acetotrophic, methanogenic bacteria and the growth of acetotrophic sulphate reducing bacteria was within the same magnitude as the CWM1 modelled rates but displayed a different trend and would have deviated even more at higher concentrations. Since fermentation products as acetate is a

form of COD, high concentrations are expected in a CW and therefore the Taylor series approximation could not be used for these two processes.

The rate was which acetate is transformed in anoxic growth of heterotrophic bacteria on COD and acetate, showed the best linearisation results. The McLaurin series approximation was similar to the CWM1 modelled, with the gradient and magnitude of the two rates being the same. From this, it can be said that it was possible to linearise two of the rates at which fermentation products as acetate is degraded.

Ammonia and ammonium nitrogen

The rate at which ammonium and ammonia nitrogen is transformed in CWs is dependent on six processes. For each of these processes, the McLaurin series approximation deviated further from the CWM1 modelled rate as the concentration of ammonium and ammonia nitrogen increased, and in some cases, the deviation was out by a factor in excess of 5700. Therefore, the McLaurin series was not used to linearise the reaction rates of ammonium and ammonia nitrogen. The Taylor series approximation had the same magnitude and gradient as the CWM1 modelled rate for almost the full concentration range. The only area in which there was a large difference between the CWM1 modelled rate, and the approximation was at a concentration of 0 mg N/L. The Taylor series approximation could be used to estimate the linear rates of ammonium and ammonia nitrogen in these processes as long as the concentration of ammonium and ammonia nitrogen is greater than 0.

Nitrate and nitrite nitrogen

The rate at which nitrate and nitrite nitrogen is transformed in CWs is dependent on three processes. For each of these processes, the McLaurin series approximation deviated further from the CWM1 modelled rate as the concentration of nitrate and nitrite nitrogen increased, and therefore the McLaurin series was not used to linearise the reaction rates of nitrate and nitrite nitrogen. The Taylor series approximation had a similar magnitude and gradient as the CWM1 modelled rate but only within a very limited range. The greatest deviation was at low concentrations of nitrate and nitrite nitrogen, and as these concentrations are common in CWs, the Taylor series approximation was not used to linearise the reaction rates of nitrate and nitrite nitrogen.

Sulphate sulphur

The rate of transformation of sulphate sulphur in CWs is dependent on one process. The McLaurin series approximation deviated further from the CWM1 modelled rate as the concentration of sulphate sulphur increased, and therefore the McLaurin series was not used to linearise the reaction rates of sulphate sulphur. The Taylor series approximation was within the same magnitude as the CWM1 modelled rate, but both the gradient and line behaviour were not the same. The only point at which they were similar was the basis concentration. Because of this, the Taylor series will deviate further at higher concentrations Therefore the Taylor series approximation was not used to linearise the reaction rates of sulphate sulphur.

Dihydrogen-sulphide sulphur

The rate at which dihydrogen-sulphide sulphur is transformed in CWs is dependent on three processes. For two of these processes (the aerobic and anoxic growth of sulphide oxidising bacteria on dihydrogen-sulphide), the McLaurin series approximation deviated further from the CWM1 modelled rate as the concentration of dihydrogen-sulphide sulphur increased. Therefore, the McLaurin series was not used to linearise these reaction rates of dihydrogen-sulphide sulphur. The Taylor series approximation for these two rates was similar in magnitude and gradient to the CWM1 modelled rate for a large section of the concentration range. The only point at which there was a large difference between the CWM1 modelled rate, and the approximation was at a concentration of 0 mg S/L. The Taylor series approximation could be used to estimate the linear rates of dihydrogen-sulphide sulphur in these processes as long as the concentration of ammonium and ammonia nitrogen is greater than 0.

The approximations of the third process (the growth of acetotrophic sulphate reducing bacteria) yielded different results. Both the Taylor series and McLaurin series approximations were within the same magnitude as the CWM1 modelled rate but had different gradients, and at higher concentrations would deviate significantly from the CWM1 modelled. For this reason, neither the McLaurin series nor the Taylor series approximations can be used in this case.

Slowly biodegradable, particulate COD

The rate of degradation of slowly biodegradable, particulate COD in CWs is dependent on one process. The McLaurin series approximation deviated further from the CWM1 modelled rate as the concentration of slowly biodegradable, particulate COD increased, and therefore the

McLaurin series was not used to linearise the reaction rates of slowly biodegradable, particulate COD. The Taylor series approximation was within the magnitude as the CWM1 modelled rate, but both the gradient and shape of the response were not the same. The only point at which they were similar was the basis concentration. Because of this, the Taylor series will deviate further at higher concentrations, therefore the Taylor series approximation was not used to linearise the reaction rates of slowly biodegradable, particulate COD.

6.4: Conclusion

The aim stated at the beginning of this chapter was to linearise the process reactions rates of CWM1 to be combined with the adapted method-of-moments techniques. Three methods were considered for the approximation of linear reaction rates: Taylor series, McLaurin series and Padé approximations. Upon investigation, it was determined that the Padé approximations and the Taylor series approximations were the same and so only the latter was discussed in detail. The linearisation approximations were applied to every rate in which the concentration of component *'i'* affected the rate at which process *'l'* proceeded.

The McLaurin series approximation proved to be a good estimate for the rate at which fermentation products as acetate was degraded in the anoxic growth of heterotrophic bacteria on fermentable, readily available COD and fermentation products as acetate. However, in no other cases was the McLaurin series an accurate approximation and in many instances was out by factors of greater than 100.

The Taylor series approximation was able to estimate the CWM1 modelled rate within a specific concentration range for the following processes:

- The rate at which dissolved oxygen was transformed through the:
    - Aerobic growth of heterotrophic bacteria on fermentable, readily biodegradable COD
    - Anoxic growth of heterotrophic bacteria on fermentable, readily biodegradable COD
    - Growth of autotrophic nitrifying bacteria on ammonium and ammonia nitrogen
    - Aerobic growth of sulphide oxidising bacteria on dihydrogen-sulphide
- The rate at which ammonium and ammonia nitrogen was transformed through:

    - Aerobic growth of heterotrophic bacteria on fermentable, readily biodegradable COD
    - Aerobic growth of heterotrophic bacteria on fermentation products, as acetate
    - Anoxic growth of heterotrophic bacteria on fermentable, readily biodegradable COD
    - Anoxic growth of heterotrophic bacteria on fermentation products, as acetate
    - Growth of autotrophic nitrifying bacteria on ammonium and ammonia nitrogen
    - Growth of fermenting bacteria
    - Growth of acetotrophic, methanogenic bacteria
    - Growth of acetotrophic sulphate reducing bacteria
    - Aerobic growth of sulphide oxidising bacteria on dihydrogen-sulphide
    - Anoxic growth of sulphide oxidising bacteria on dihydrogen-sulphide
- The rate at which nitrate and nitrite nitrogen transform through the:
    - Aerobic growth of heterotrophic bacteria on fermentation products, as acetate
    - Anoxic growth of heterotrophic bacteria on fermentation products, as acetate
    - Growth of acetotrophic sulphate reducing bacteria
    - Anoxic growth of sulphide oxidising bacteria on dihydrogen-sulphide
- The rate at which dihydrogen-sulphide sulphur is transformed through the:
    - Aerobic growth of sulphide oxidising bacteria
    - Anoxic growth of sulphide oxidising bacteria

In other cases, the Taylor series approximation was in the same range in terms of magnitude, but the gradient was different for the full range and therefore was not a good approximation of the CWM1 modelled rate. This was true for the follow rates.

- The rate at which fermentable, readily available COD is transformed through:
    - Aerobic growth of heterotrophic bacteria on fermentable, readily available COD
    - Aerobic growth of heterotrophic bacteria on fermentation products as acetate
    - Growth of fermenting bacteria
- The rate at which fermentation products, as acetate, is transformed through:
    - Growth of acetotrophic, methanogenic bacteria
    - Growth of acetotrophic, sulphate reducing bacteria
- The rate at which nitrate and nitrite nitrogen is transformed through:
    - Anoxic growth of sulphide oxidising bacteria on dihydrogen-sulphate sulphide

- The rate at which sulphate-sulphide is transformed through:
    - Growth of acetotrophic, sulphate reducing bacteria
- The rate at which dihydrogen-sulphate is transformed through:
    - Growth of acetotrophic, sulphate reducing bacteria

There were two cases in which the Taylor series approximation was in the same magnitude and had the same gradient as the CWM1 modelled rate: the rate at which fermentation products, as acetate, were transformed through the anoxic growth of heterotrophic bacteria on fermentable, readily available COD and the anoxic growth of heterotrophic bacteria on fermentation products as acetate. For these two cases the linearisation technique applied was successful.

While there was some success in the linearisation of the reaction rates of CWM1, it was not achievable for all components in all processes. In order for the CWM1 biokinetic model to be combined with the adapted method-of-moments technique, all rates need to be first-order. This was not achieved using the Taylor series approximation or the McLaurin series approximation. Without the combination of the hydraulic modelling and the kinetic modelling, it is not possible to calibrate the full technique on a CW and only the hydraulic modelling part of the technique can be validated. More work needs to be done to determine if there are specific ranges in which the Taylor series approximation could be effective in linearising the reaction rates or to determine if stepwise Taylor series approximation could be used. It is not recommended that the McLaurin series approximation technique is used. Investigation into the use of other linearisation techniques, could be studied in future work.

Chapter 7: Validation of the modelling techniques on a small-scale indoor reactor

Section 7.3 has been published in Science of the Total Environment and was peer reviewed prior to publication (Stephenson, R., Sheridan, C. and Kappelmeyer, U. (2020) 'A curve-shift technique for the use of non-conservative organic tracers in constructed wetlands', *Science of The Total Environment*. Elsevier B.V., 752, p. 141818. doi: 10.1016/j.scitotenv.2020.141818). The contribution of the co-authors towards the work is primarily that of supervision or collaboration and the experimental work and write-up was conducted by the author of this thesis.

7.1: Introduction

The modelling of CWs is dependent on accurate characterisation of the hydraulic behaviour of the fluid flowing through the CW. The theory and mathematical basis behind the two residence time distribution techniques have been discussed in previous chapters. The next step is to validate these techniques with experimental data. The previous chapter showed that linearisation was not possible for the majority of the reaction rates in CWM1. However, it is still possible to validate the time section of the adapted method-of-moments technique. Validation of the adapted method-of-moments technique and curve-shift technique requires experimental data from residence time distribution studies. Impulse-response tracer studies were conducted for the validation of the adapted method-of-moments technique and step-change tracer studies were conducted for the validation of the curve-shift technique. Experimental data and the application of the techniques to this data is given in this Chapter.

7.2: Method-of-Moments Adaptation

To evaluate the effectiveness of the time section of the adapted method-of-moments technique, impulse-response tracer studies were conducted on two types of systems: a set of columns filled with gravel (similar to that which is used in CWs), and a small-scale CW inside a green house. In both cases uranine was the tracer used. A detailed breakdown of how the experiments were conducted and a description of each of the systems is given in Section 3.1.1.

7.2.1 Impulse-Response Tracer Studies Conducted on Vertical Flow Columns

The first set of experiments conducted to test the time section of the adapted method-of-moments technique was on a set of three identical columns filled with pea gravel. A picture of the columns can be seen in Figure 7.1. This experiment was conducted to assess the effectiveness of the technique in describing the flow of a system which did not contain plants, and where the non-idealities come from the heterogeneity of the system. The columns were made of orange PVC and covered with a lid made of the same material. The packing material of the columns was pea gravel which had a diameter of 2 mm-8 mm and a void fraction of 0.36. The columns were identical in size with the dimensions being 0.15 m x 0.4 m (d x h). Each column was filled with the packing media to a height of 0.37 m. The system consisted of two ports, the inlet port at a height of 0.04 m above the base and the outlet port at a height of 0.37 m above the base. The water volume of the system was 2.16 l. A peristaltic pump was used to deliver water to the columns at a continuous and consistent flow rate of 31 ml/min. The nominal residence time of each of the columns was 79 minutes and the flow velocity was 0.11 m/s. At this velocity the flow was laminar and therefore the information inferred from these tests can be applied to the system at any other flow rate in the laminar range (Levenspiel, 1999). Samples were taken every 4 minutes, which is just over 5% of the nominal residence time and considered frequent enough to accurately capture the hydraulic behaviour of the system. Samples were taken until the concentration of tracer reached background concentrations again and more than 3 times the nominal residence time passed. Details of how the experiment was conducted, as well as the analytical methods used are given in Chapter 3.

***Figure 7.1**: Picture of the vertical flow gravel columns on which impulse-response tracer studies were conducted.*

Results and Discussion

In Figure 7.2 the data from the impulse-response tracer study conducted on the gravel columns is displayed. The black line indicates the mean behaviour of the three vertical flow columns, and the shaded, grey area indicates the standard deviation of the three columns. The peak of the tracer came through the system at a time of 40 minutes, which is just greater than half the nominal residence time. The peak arrived suddenly, with the concentration increasing rapidly from background concentrations of 1.49 ppb to 44 ppb in 24 minutes. This rapid increase, and the time at which it reaches the outlet, indicates that the fluid passes through the system more quickly than expected. There was a long tail after the tracer concentration peaks and it took 240 minutes (from the peak) for the tracer concentration to return to background concentrations. This long tail indicates a large amount of dispersion and micro-mixing in the system. This could be due to the heterogenous nature of the gravel (Suliman, Futsaether and

Oxaal, 2007) but is also a known behaviour of packed bed reactors(Levenspiel, 1999).

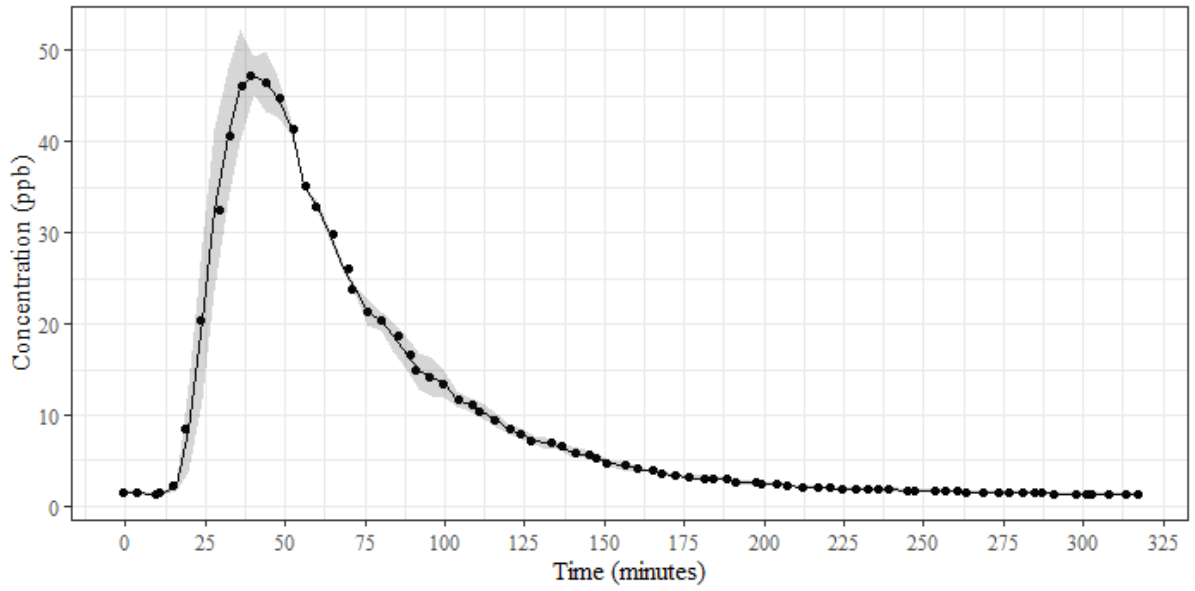

***Figure 7.2**: Results from the impulse-response tracer study conducted on gravel column triplicates*

In Table 7.1 the hydraulic parameters determined from the impulse-response tracer study on the three vertical flow columns are displayed. The peak of the impulse-response curve was at 40 minutes. The mean residence time, as per the definition given in Section 2.8.4, for the vertical flow columns was 80.9 minutes. This is only 2.4% higher than the nominal residence time of the systems. The mean residence time is close to the nominal residence time as a result of a combination of two factors. The first phenomenon is that the peak of the impulse-response curve, which is the highest concentration of tracer, reached the outlet of the system at approximately half the nominal residence time. If this were the only influence on mean residence time, the mean residence time would be significantly lower than the nominal residence time. However, there is a second phenomenon which affects the mean residence time and that is the long tail of the response curve. Dispersion causes the tracer to spread out, which in turn causes a long tail in the impulse-response curve. This has an effect of increasing the mean residence time of the system. The combination of these two factors, one favouring a smaller mean residence time and the other a larger mean residence time means that the actual mean residence time ends up being quite close to the nominal residence time. This is an indication of how a system can display non-ideal behaviour and yet the mean residence time of the system does not show the non-ideal nature.

The number of tanks in series which can be used to describe this system is 1.90. This value is close to 1 (as opposed to infinity) which indicates a large amount of mixing in the system. The long tail of the response is an indication of a large amount of micro-mixing which would lead to an N value close to 1. This micro-mixing could be due to the heterogenous nature of the gravel; a variation in grain size leads to a variation in hydraulic conductivity, and one of the results is micro-mixing (Suliman, Futsaether and Oxaal, 2007). The effective volume ratio of the gravel columns is 1.02. This is not surprising as the mean residence time is very close to the nominal residence time. This value indicates that while there may be dispersion in the system, the full volume of the columns is still being used. The hydraulic efficiency of the columns is 0.485. This parameter factors in the effective volume ratio and the extent of mixing in a system. While the effective volume ratio was higher than 1 (which is a good thing) the small N value, indicative of lots of micro-mixing, means that the system only has a hydraulic efficiency of 48.5%.

***Table 7.1**: Hydraulic parameters obtained from the impulse response tracer studies conducted on gravel column triplicates*

Parameter	**Value**	**Unit**
$\mathbf{t_m}$	80.9	min
$\boldsymbol{\sigma^2}$	3572	min^2
N	1.90	-
λ	0.485	-
e	1.02	-

To validate the time section of the method-of-moments technique, the area under the E(t) vs time curve was broken up into 5 portions of approximately equal area (~20%). The limits of each section were selected such that the areas were approximately equal. In Figure 7.3, the 5 portions into which the area under the E(t) curve was divided into, is presented. The black line is the average response of the three vertical flow columns and the grey shaded area indicates the standard deviation, as in Figure 7.2. Each of the green shaded areas represents approximately 20% of the area under the curve and therefore approximately 20% of the fluid in the system. The specific percentages as well as the mean residence time and variance for each of the shaded portions can be found in Table 7.2.

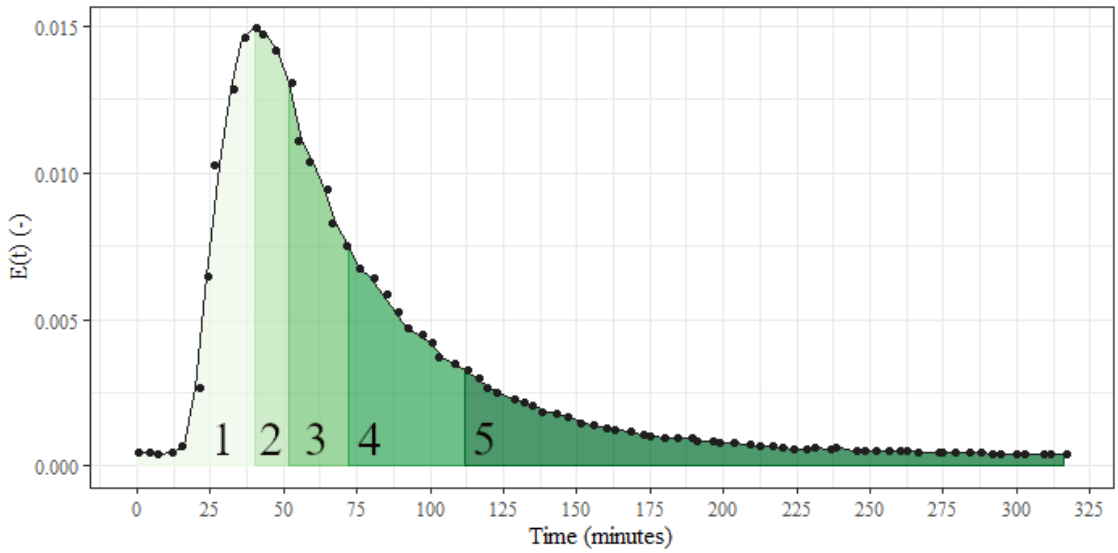

***Figure 7.3**: Results from an impulse-response tracer study conducted on the gravel column triplicates, divided into 5 portions*

Portion 1 of the graph, which was between 0 minutes and 40 minutes had a volume percentage of 23% and a mean residence time of 31 minutes. This means that 23% of the fluid in the system spent an average of 31 minutes in the column before leaving. The nominal residence time of the potion was determined to be 24.22 minutes. The mean residence time was almost double the nominal residence time and this indicates that this portion of fluid took longer to move through the system than expected. The result of this shorter time is that the reaction time during which contaminants can be broken down, is reduced and the outlet concentration of contaminants is higher than if there was ideal plug flow.

Portion 2 of the graph was between 40 minutes and 52 minutes, which was only 12 minutes. While this portion represented a similar fraction of fluid compared to all the other portions, the time period over which it is measured was the smallest, at only 12 minutes. This is because the peak came through in this portion of fluid. This portion had a volume percentage of 17% and a mean residence time of 45.85 minutes. This means that 17% of the volume spent that amount of time in the system. In comparison to the nominal residence time of the portion, which was 51.96 minutes, the mean residence time is 12% lower. This indicates that portion 2 of the fluid spent less time in the system than expected. The consequence of this is that there is less time for contaminants to be broken down in this portion than expected and this will influence the overall ability of the system to break-down contaminants.

The third portion lies between 52 minutes and 72 minutes, a time difference of 20 minutes. This portion has a mean residence time of 61.05 minutes and represents 20% of the total fluid

of the system. The nominal residence time of portion 3 was 65.80 minutes. This is 4 minutes higher than the mean residence time for the portion. Like portion 1 and portion 2, a lower mean residence time than nominal residence time means that the time during which contaminant degradation can take place is less than expected and therefore the expected outlet concentration for the full system is affected.

Portion 4 represented 20% of the fluid of the system and was between 52 minutes and 112 minutes, which was a full 60-minute time period. Portion 4 had a mean residence time of 89.15 minutes. The nominal residence time of the system is 86.03 minutes. Portion 4 is the first portion where the mean residence time was longer than the nominal residence time. The consequence of this was that the contaminants in this portion of fluid spent longer in the system than expected which meant that there is more contaminant degradation in this section than expected. This will have an impact on the contaminant reduction of the full system.

The final portion was between 112 minutes and 316 minutes and was the longest time period of the five sections, at 204 minutes. This portion represented 20% of the fluid in the system and had a mean residence time of 177.7 minutes. The mean residence time of this portion was 41% greater than the nominal residence time of the portion which was 126.1 minutes. This means that there is more time for contaminant degradation than expected which will improve the contaminant removal of the overall system.

The original data and code used to produce Figure 7.2 and Figure 7.3 can be found in Appendix F and Appendix G respectively.

***Table 7.2**: Hydraulic parameters for 5 portion obtained from the impulse response tracer studies conducted on the gravel vertical flow columns.*

Portion	Parameter	Value	Unit
1	t_1	31.00	min
	τ_1	24.22	min
	γ_1	0.23	(-)
	σ^2_1	11.25	min^2
2	t_2	45.85	min
	τ_2	51.96	min
	γ_2	0.17	(-)
	σ^2_2	40.35	min^2
3	t_3	61.05	min
	τ_3	65.80	min
	γ_3	0.20	(-)
	σ^2_3	186.08	min^2
4	t_4	89.15	min
	τ_4	86.03	min
	γ_4	0.20	(-)
	σ^2_4	26.47	min^2
5	t_5	177.70	min
	τ_5	126.10	min
	γ_5	0.20	(-)
	σ^2_5	634.21	min^2

The data obtained from dividing the residence time distribution curve can be used in the adapted method-of-moments technique. This is displayed in Equation 7.1.

$$C_{out} = \sum_{j=1}^{n} \gamma_j \, C_{in} e^{-kt_j} \tag{7.1}$$

For this case n=5 (the number of segments that the RTD was divided into) and therefore Equation 7.1 becomes Equation 7.2.

$$C_{out} = \sum_{j=1}^{5} \gamma_j \, C_{in} e^{-kt_j} \tag{7.2}$$

If Equation 7.2 is expanded out, it becomes Equation 7.3.

$$C_{out} = \gamma_1 \, C_{in} e^{-kt_1} + \gamma_2 \, C_{in} e^{-kt_2} + \gamma_3 \, C_{in} e^{-kt_3} + \gamma_4 \, C_{in} e^{-kt_4} + \gamma_5 \, C_{in} e^{-kt_5} \tag{7.3}$$

The mean residence time for each portion and the nominal residence time for each portion was used in Equation 7.3 to show the effect of using the expected or ideal hydraulic behaviour in the model compared to hydraulic behaviour obtained from tracer studies. The kinetic modelling of the system was based on a theoretical component, with a first-order rate constant *'k'*. The inlet concentration of the theoretical compound was 10 g, and the first-order rate constant was 0.1 min^{-1}.

The nominal residence time for each section, along with the respective fraction of fluid, was substituted into Equation 7.3 and this yielded Equation 7.4. The final outlet concentration of the theoretical concentration is given in Equation 7.5.

$$C_{out} = (0.23)(10)e^{-(0.1)(24.22)} + (0.17)(10)e^{-(0.1)(51.96)} + (0.2)(10)e^{-(0.1)(65.80)} + (0.2)(10)e^{-(0.1)(86.03)} + (0.2)(10)e^{-(0.1)(126.1)} \tag{7.4}$$

$$C_{out} = \ 0.204 + 9.42 * 10^{-3} + 2.78 * 10^{-3} + 3.67 * 10^{-4} + 6.68 \ * 10^{-6} \tag{7.5}$$

$$C_{out} = \ 0.217 \ g$$

The mean residence time for each section, along with the respective fraction of fluid, was substituted into Equation 7.3 and this yielded Equation 7.6. The final outlet concentration of the theoretical concentration is given in Equation 7.7.

$$C_{out} = (0.23)(10)e^{-(0.1)(31.0)} + (0.17)(10)e^{-(0.1)(45.85)} + (0.2)\ (10)e^{-(0.1)(61.05)} + (0.2)\ (10)e^{-(0.1)(89.15)} + (0.2)\ (10)e^{-(0.1)(177.70)} \tag{7.6}$$

$$C_{out} = 0.104 + 0.017 + 4.46\ 10^{-3} + 2.69\ 10^{-4} + 3.83\ 10^{-8} \tag{7.7}$$

$$C_{out} = 0.126\ g$$

The results of Equation 7.5 and Equation 7.7 show that it is possible to use this as a hydraulic modelling technique in situations where the kinetic modelling is based on first-order rate laws. By comparing the two outlet concentration values it can be seen that the outlet concentration calculated using the nominal residence times is greater than the outlet concentration calculated using the mean residence times. This indicates that more contaminant removal was predicted by using the mean residence time (0.126 g) instead of the nominal residence time (0.217 g). A shorter nominal residence time than mean residence time for portion 1 meant that the outlet concentration for that section was double for the nominal residence time than the mean residence time, even though the latter was not double the former. The outlet concentration of a contaminant is not directly proportional to the reaction time, because of the exponent, and therefore, even though the nominal residence time for portion one was half of the mean residence time, the contaminant removal predicted using the mean residence time was not half of that predicted using the nominal residence time. This highlights the effect that residence time has on the contaminant removal in CWs.

7.2.2: Impulse-Response Tracer Studies Conducted on a HSSF Constructed Wetland

The second set of experiments conducted to test the time section of the adapted method-of-moments technique were conducted on a small-scale horizontal sub-surface flow constructed wetland in a greenhouse at Hemholtz Centre for Environmental Research – UFZ, in Leipzig Germany. A schematic of the system can be found in Figure 7.4. This experiment was conducted to assess the effectiveness of the technique in describing the flow of a system in which the non-ideal behaviour comes from the heterogenous nature of the gravel and the plant root structure, like a typical wetland. The packing material of the wetland was pea gravel with a diameter of 2 mm-8 mm and a void fraction of 0.36. The wetland dimensions were 1 m x 0.21 m x 0.15 m (L x H x W). The system was planted with *Juncus effuses*. The volume of the system was 10 L and the inlet flowrate was 2.5 L/hour. This resulted in a nominal residence time of 4 hours. At this velocity the flow is still laminar and therefore the information inferred from these tests can be applied to the system at any other flow rate in the laminar range (Levenspiel, 1999). A GGUN-FL30 fluorometer was used for automatic, inline detection of uranine at the outlet of the wetland, recording every 3 minutes. Full details of how the experiment was conducted, as well as analytical methods are detailed in Chapter 3.

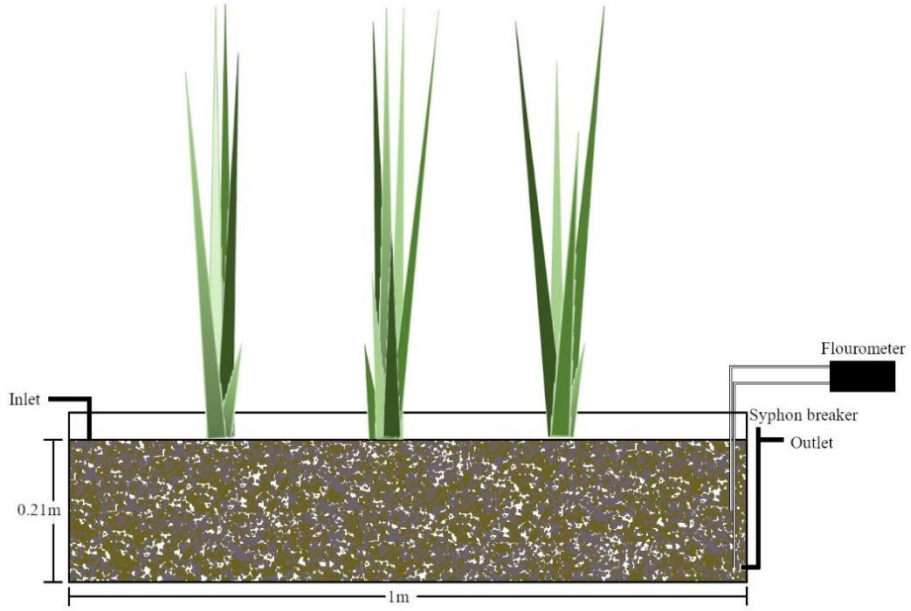

***Figure 7.4**: Schematic of the HSSF CW on which impulse-response and step change tracer studies were conducted*

Results and Discussion

In Figure 7.5 the data from the impulse-response tracer study conducted on the CW is displayed. The tracer started to arrive at the outlet of the CW after 2.4 hours. From this figure it can be seen that there are multiple peaks in the response of the system to the impulse of tracer. This indicates that the fluid took multiple flow paths through the wetland. The highest peak of the tracer came through the system at a time of 4.4 hours, which is slightly higher than the nominal residence time. A second peak arrived at 4.75 hours, a third peak at 6.5 hours and a fourth peak at 7.55 hours. As none of these peaks arrived at the outlet earlier than the nominal residence time of the system, it cannot be said that short-circuiting took place, as short-circuiting implies that fluid takes a path through the wetland, which is shorter, and therefore faster than, the bulk of the fluid. However, it is indicative of separate and preferential flow paths in the system. There is a long tail after the final peak and the tracer concentration only reached background concentrations again after 13.7 hours.

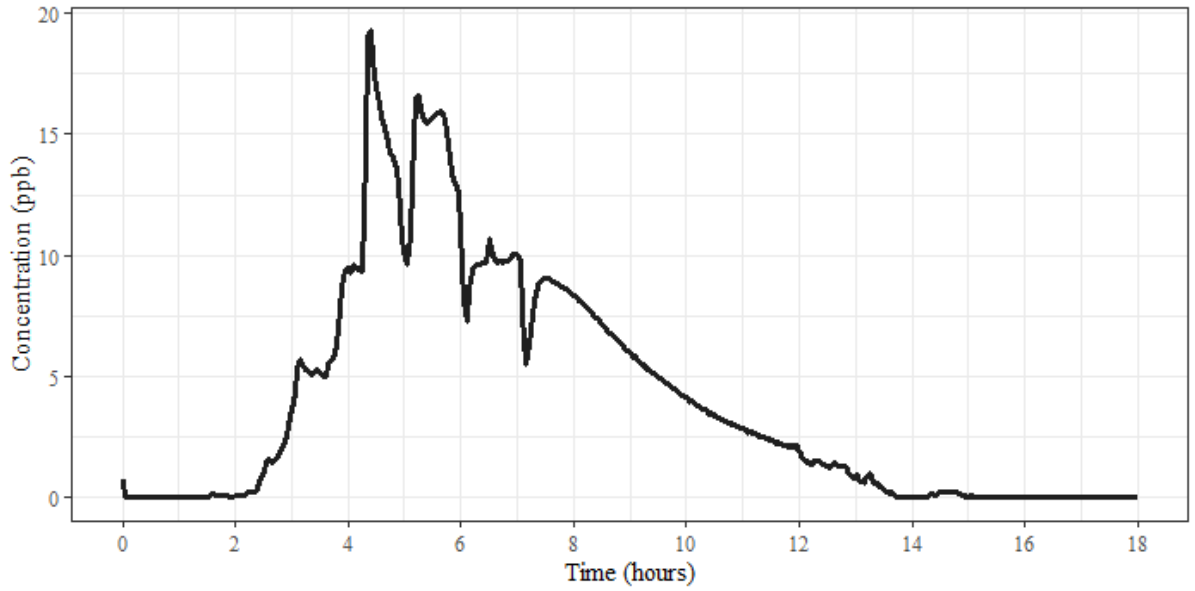

***Figure 7.5**: Results from the impulse-response tracer study conducted on a small-scale HSSF CW*

In Table 7.3 the hydraulic parameters determined from the impulse-response tracer test conducted on a CW are shown. The mean residence time of the system is 6.67 hours. This is 66.75% higher than the nominal residence time of the system. This indicates that the fluid took longer to pass through the system than expected.

The number of tanks-in-series which can be used to describe the small-scale CW is 7.9. This is larger than the TIS values obtained for HSSF CWs found in literature (Kadlec, 2007). A large N values indicates that there is minimal mixing in the system and the CW behaves more like a PFR than a CSTR. This is preferred for a CW (Suliman, Futsaether and Oxaal, 2007). The effective volume ratio of the system is greater than 1. From this it can be determined that the full volume of CW is being used. The hydraulic efficiency of this system is 1.45. This is high for a CW but is due to the large N value and effective volume ratio.

***Table 7.3**: Hydraulic parameters obtained from the impulse response tracer studies conducted on the CW*

Parameter	Value	Unit
$\mathbf{t_m}$	6.67	hour
$\boldsymbol{\sigma^2}$	5.6	$hour^2$
N	7.9	-
λ	1.45	-
e	1.65	-

To validate the time section of the method-of-moments technique on the small-scale CW, the area under the E(t) vs time curve was broken up into 5 portions. This can be seen in Figure 7.6. Each shaded area represents approximately 20% of the area under the curve and therefore approximately 20% of the fluid in the system. The specific percentages as well as the mean residence time and variance for each portion can be found in Table 7.4.

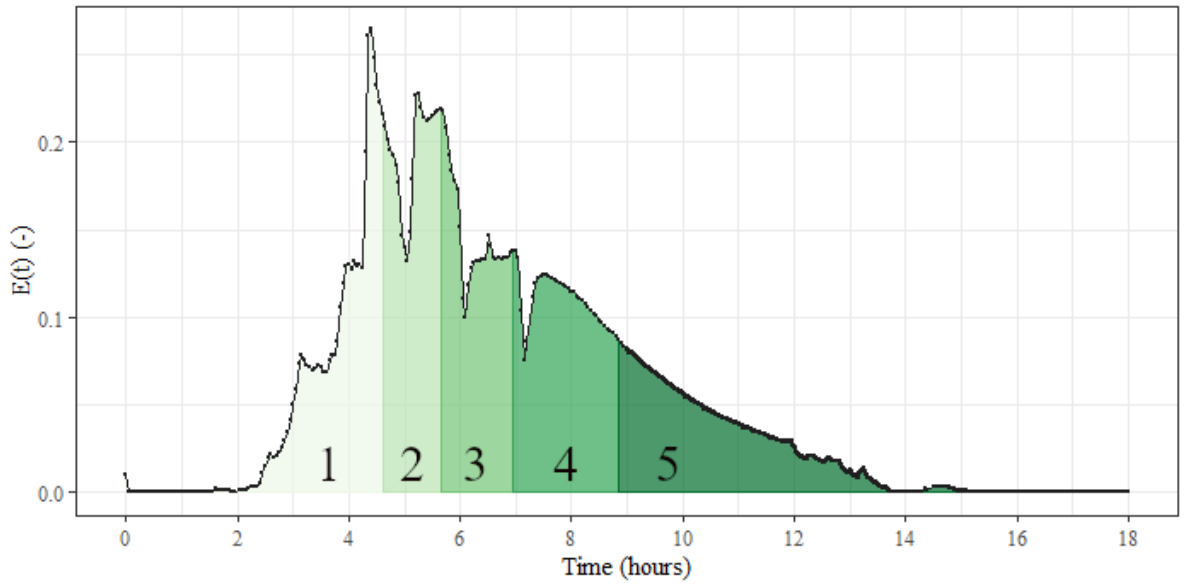

***Figure 7.6**: Results from an impulse-response tracer study conducted on the CW, divided into 5 portions*

Portion 1 was between 0 hours and 4.6 hours and has a mean residence time of 3.90 hours. The mean residence time was very similar to the nominal residence time for the portion. This indicates that the degradation determined using the nominal residence time is a good indication for what is actually taking place in the bed.

Portion 2 had a mean residence time of 5.14 hours and lies between 4.60 hours and 5.65 hours. This time period of just more than 1 hour represents 20% of the fluid. The nominal residence time of the fluid in portion 2 was 5.42 hours which is 4% lower than the mean residence time. This means that the fluid in this portion spent slightly longer in the system than expected and the contaminant degradation for this section will be slightly greater than expected. The first and second peak of the response occurred in portion 2.

Portion 3 was between 5.65 hours and 6.95 hours. This portion had a mean residence time of 6.25 hours and the nominal residence time was 6.41 hours. The difference between the two residence times was 0.16 hours with the nominal residence time being higher. This means that the fluid in this portion spent less time in the system than expected and therefore the contaminant removal in this section will be less than expected. The third peak of the response occurred in portion 3.

Portion 4 represents 21% of the fluid and lies between 6.95 hours and 8.85 hours. This portion has a mean residence time of 7.86 hours. The nominal residence time of this section was 7.78 hours which is 1% lower than the mean residence time. The two residence times are so close that it can be said that this section of fluid spent the expected amount of time in the system.

The final portion was between 8.85 hours and 18 hours, which is the largest time period of the 5 portions, with a duration of 9.15 hours. This portion represents 20% of the fluid in the system as has a mean residence time of 10.49 hours. The nominal residence time of this section was 9.61 hours. This means that the fluid in this section spent 9% longer in the system than expected. This means that there will be greater contaminant removal in this section than expected.

The original data and code used to produce Figure 7.5 and Figure 7.6 can be found in Appendix H and Appendix I, respectively.

***Table 7.4**: Hydraulic parameters for 5 portions obtained from the impulse response tracer studies conducted on the CWs.*

Portion	Parameter	Value	Unit
1	t_1	3.90	hour
	τ_1	3.76	hour
	γ_1	0.21	(-)
	σ^2_1	0.070	$hour^2$
2	t_2	5.14	hour
	τ_2	5.42	hour
	γ_2	0.2	(-)
	σ^2_2	0.333	$hour^2$
3	t_3	6.25	hour
	τ_3	6.42	hour
	γ_3	0.19	(-)
	σ^2_3	1.08	$hour^2$
4	t_4	7.86	hour
	τ_4	7.78	hour
	γ_4	0.21	(-)
	σ^2_4	3.32	$hour^2$
5	t_5	10.49	hour
	τ_5	9.60	hour
	γ_5	0.19	(-)
	σ^2_5	8.40	$hour^2$

The data obtained from dividing the residence time distribution curve from the tracer testes conducted on a HSSF CW can be used in the adapted method-of-moments technique. This is displayed in Equation 7.8 to Equation 7.11. The mean residence time for each portion and the nominal residence time for each portion was used in Equation 7.3 to show the effect of using

the expected or ideal hydraulic behaviour in the model compared to hydraulic behaviour obtained from tracer studies. The kinetic modelling of the system was based on a theoretical component, with a first-order rate constant *'k'*. The inlet concentration of the theoretical compound was 10 g and the first-order rate constant was 0.1 min^{-1}.

The nominal residence time for each section, along with the respective fraction of fluid, was substituted into Equation 7.3 and this yielded Equation 7.8. The final outlet concentration of the theoretical concentration is given in Equation 7.9.

$$C_{out} = (0.21)(10)e^{-(0.1)(3.76)} + (0.2)(10)e^{-(0.1)(5.42)} + (0.19)(10)e^{-(0.1)(6.42)} + (0.21)(10)e^{-(0.1)(7.78)} + (0.19)(10)e^{-(0.1)(9.60)} \quad (7.8)$$

$$C_{out} = 1.44 + 1.16 + 1.00 + 0.96 + 0.72 \quad (7.9)$$

$$C_{out} = 5.30\ g$$

The mean residence time for each section, along with the respective fraction of fluid, was substituted into Equation 7.3 and this yielded Equation 7.10. The final outlet concentration of the theoretical concentration is given in Equation 7.11.

$$C_{out} = (0.21)(10)e^{-(0.1)(3.90)} + (0.2)(10)e^{-(0.1)(5.14)} + (0.19)(10)e^{-(0.1)(6.25)} + (0.21)(10)e^{-(0.1)(7.86)} + (0.19)(10)e^{-(0.1)(10.49)} \quad (7.10)$$

$$C_{out} = 1.42 + 1.20 + 1.02 + 0.96 + 0.67 \quad (7.11)$$

$$C_{out} = 5.26\ g$$

The results of Equation 7.9 and Equation 7.11 show that it is possible to use this as a hydraulic modelling technique in situations where the kinetic modelling is based on first-order rate laws. By comparing the two outlet concentration values it can be seen that the outlet concentration calculated using the nominal residence times is greater than the outlet concentration calculated using the mean residence times. This indicates that more contaminant removal was predicted by using the mean residence time (5.26 g) instead of the nominal residence time (5.30 g). However, the contaminant removal for both was similar and this is due to the mean residence time and the nominal residence time for each of the portions being very close.

Conclusion

The time section of the adapted method-of-moments technique was tested on data from two impulse-response tracer studies. The first was conducted on three columns filled with pea gravel and the second was conducted on small-scale CW in a greenhouse. The area under the curve of the impulse-response data for each experiment was divided into five portions, each with approximately equal area. This technique was combined with a theoretical components and reaction rate to display the full process of using the technique. The results of using this technique with the mean residence time and the nominal residence time were presented. It is possible to divide the area under the residence time distribution curve into more than, or less than, five portions. Increasing the number of portions allows for more in-depth analysis and investigation but is more time consuming.

The time portions can also be divided according to equal time periods, rather than equal areas under the curve. The benefit of equal time periods allows the researcher to investigate the contribution of each batch of fluid to the overall breakdown of contaminants in the system, as they are all equal in volume and therefore have the same starting amount of contaminant. However, dividing the area according to time periods allows the researcher to investigate in which time period the bulk flow occurs and the contribution to contaminant degraded in each time period.

The content presented in this section was used to display the validation and scope of use of the adapted method-of-moments technique with a theoretical first-order rate law. In the following section the validation of the curve-shift technique is presented. The content presented in Section 7.3 has been published in the Science of the Total Environment (Stephenson, Sheridan and Kappelmeyer, 2020) which is an international multi-disciplinary, peer-reviewed journal.

7.3: The Curve Shift Technique

To evaluate the effectiveness of the curve-shift technique, step-change tracer studies were conducted on a small-scale wetland inside a green house. Uranine was used as the conservative tracer and benzoate was used as the non-conservative tracer since uranine is largely conserved. A detailed breakdown of how tests were conducted, and a description of the constructed wetland can be found in Chapter 3, section 3.2.

The data and technique given in this section has been published previously by *Stephenson et al. (2020)* in the Journal of Water Process Engineering.

A non-linear least-squares regression analysis was run in RStudio on the experimental data collected for each of the tracers. The experimental data for uranine was compared a modelled result using the advective-dispersive transport equation *without decay* (Equation 4.17) and the experimental data for benzoate was compared with the modelled results using the advective-dispersive transport equation *with decay* (Equation 4.21). The experimental data for both tracers was in the form of the cumulative distribution curve for the uranine and benzoate. The parameters used to fit these equations to the respective experimental data are given in Table 7.5. This was done in order to determine the values of the retardation factor, R, and the dispersion coefficient, D, for both tracers; and μ for the non-conservative tracer. In previous studies, it has been assumed that R=1, meaning that the solute is non-sorbing, but from the data collected it was clear that this was not the case. The graphical results of the non-linear least squares regression analysis for conservative tracer, uranine, and non-conservative tracer, benzoate, can be found in Figure 7.7 a) and 7.7 b), respectively. In Table 7.6 the values of R, D and μ obtained from the non-linear least-squares regression analysis can be found (Stephenson, Sheridan and Kappelmeyer, 2020).

Table 7.5: *Parameters for the analytical solution of the advective-dispersive transport equation solved for the conservative tracer (uranine) and the non-conservative tracer (benzoate)*

Parameter	**Symbol**	**Value for uranine**	**Value for benzoate**
Fluid velocity	u (m/hour)	0.05	0.05
Inlet concentration	Cin (-)	1	1
Initial concentration	C1 (-)	0.00272253	0.00272253
First-order decay	μ	0	0.01
Zero-order production	γ	0	0
Starting value for hydrodynamic dispersion	D	0.012	0.00014
Starting value for the retardation factor	R	7	4

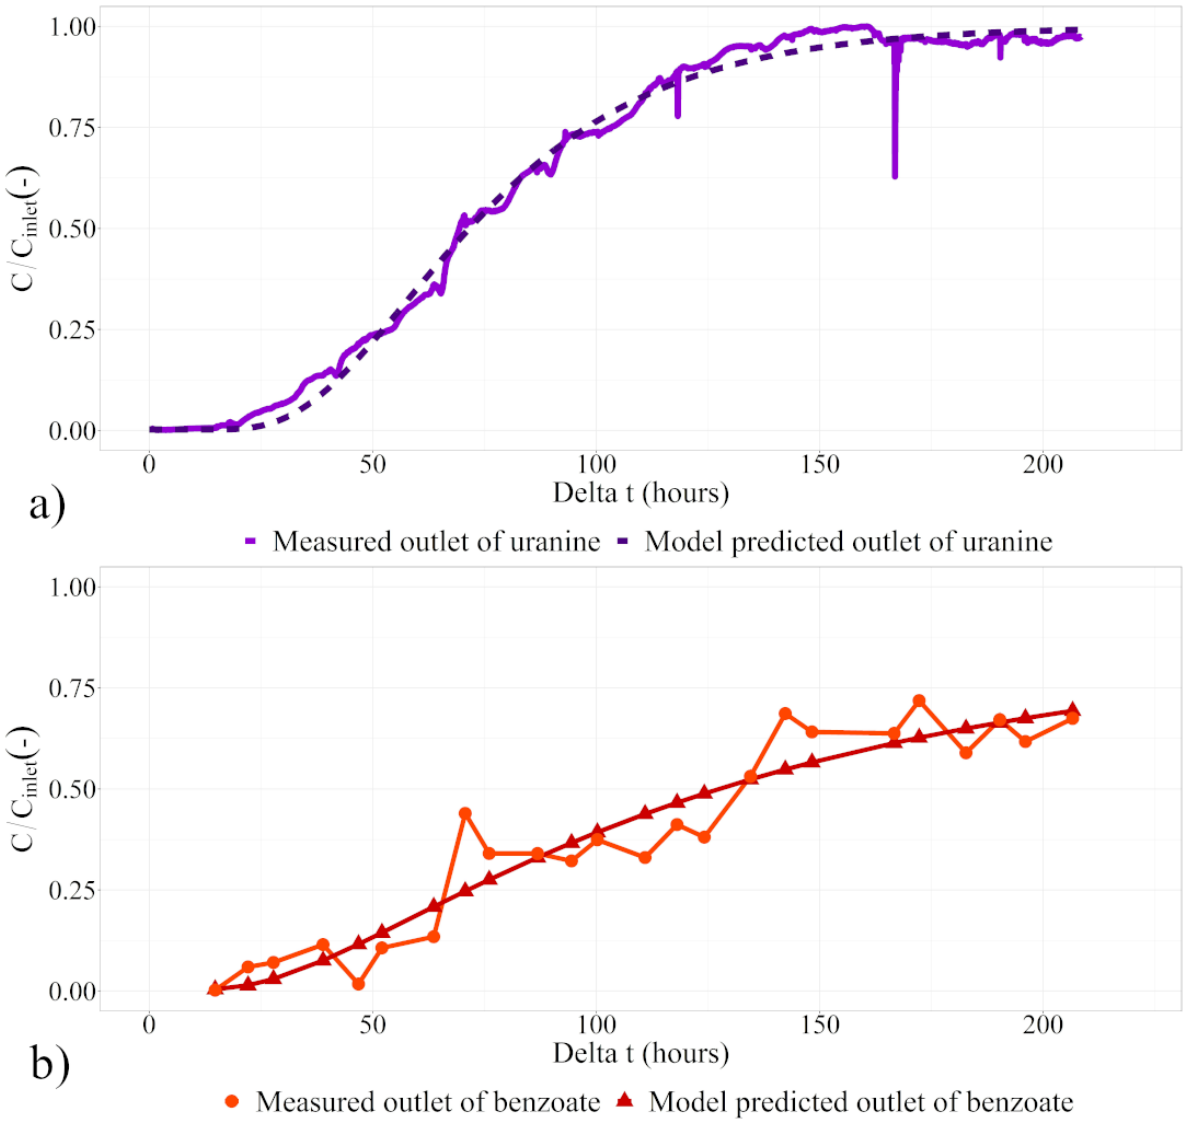

Figure 7.7: *Results of the non-linear least squares regression analysis for conservative tracer, uranine, and non-conservative tracer, benzoate*

Table 7.6: *Parameters obtained from the least-squares regression analysis*

Tracer	R	D	μ	Correlation coefficient	p-value
Uranine	3.550119	0.005961	-	0.997	< 2.2e-16
Benzoate	5.553886	0.021036	0.00949	0.949	1.723e-12

The original data used to produce Figure 7.7 can be found in Appendix J and K. The code used to generate Figure 7.7 and determine the hydraulic parameters for each tracer can be found in Appendix L.

7.3.1: Comparison of the Results Obtained from the Non-Linear Least-squares Analysis for Uranine and Benzoate.

The retardation factor of uranine obtained in the non-linear least-squares analysis is lower than that of benzoate. This is backed up by solubility data for both substances. The solubility of benzoate increases with increasing pH and at the pH of experimental conditions is approximately 29 mg/L (Avdeef and Berger, 2001) and uranine has a solubility of greater than 500 mg/mL (Merck KGaA, 2017). This indicates that uranine is more soluble than benzoate. The less soluble tracer is more likely to be willing to leave the fluid and be adsorbed onto the wetland substrate, which would result in a higher retardation factor in the transport equation. The retardation factor of benzoate is higher than that of uranine which indicates that it is more likely to be adsorbed. The retardation factor for uranine is calculated to be greater than 1, which indicates that sorption does take place. However, inlet concentrations are reached, and it is assumed that the sorption equilibrium is reached and therefore minimal tracer is lost to this mechanism. The hydrodynamic dispersion co-efficient of benzoate obtained in the non-linear least-squares analysis is greater than that of uranine. Molecules of lower molecular weight diffuse faster (Maderuelo, Zarzuelo and Lanao, 2011) and the molar mass of uranine is higher than that of benzoate, being 332.31 g/mol and 121.11 g/mol, respectively. This indicates than benzoate should have a higher hydrodynamic dispersion coefficient than uranine. This is in line with what was found in the regression analysis where the D value for benzoate is approximately 3 times higher than that of uranine.

The results obtained in the non-liner least-squares regression were then used to develop the technique to map the non-conservative tracer response onto the conservative tracer response.

7.3.2: Comparison of Least-squares Regression Model with Experimental Data

Figure 7.8 a) gives the cumulative distribution response (F(t)) for the conservative tracer, uranine, and the non-conservative tracer, benzoate, in the step-change experiment. After approximately 150 hours stable concentrations of both uranine and benzoate have been reached. The difference in the response of each of the substances is due to two major factors. Firstly, the degradation of benzoate, the non-conservative tracer which is indicated by a stable F(t) value, at an average of 0.654, which is significantly lower than 1. This shows that there has been a decay of benzoate, which is expected due to its non-conservative nature. The stable

normalized concentration of uranine is 0.971 which is in line with the assumption that it is a conservative tracer. The second major factor is the delayed response of the benzoate curve which is due to retardation as can be seen in the time interval 50 hours to 150 hours in Figure 7.8 a). This indicates that the transport of benzoate is slower than that of the uranine. In Figure 7.8 b) the comparison of the responses obtained from the non-linear least-squares regression is provided. Because of the noise in the experimental data, the results displayed in Figure 7.8 b) were subsequently used for the curve-shift technique. The hydraulic performance indices obtained from the experimental data and regressions model data can be found in Table 7.7.

Table 7.7. *Hydraulic performance indices of the experimental data and regression models for the step-change experiment.*

	t_m (hours)	N	e	λ	σ^2	Pe
Conservative tracer data	77.99	4.25	1.08	0.8283	1430.99	
Conservative tracer model	78.99	4.63	1.09	0.8601	1348.19	8.3879
Non-conservative tracer data	115.71	1.75	1.60	0.6888	7649.12	
Non-conservative tracer model	116.09	1.77	1.61	0.7030	7601.41	2.397

7.3.3: Shifting the Tracer Curves

Four techniques were considered for shifting the conservative and non-conservative tracer response curves. These are discussed below.

Mapping 1:

The data from the non-conservative tracer regression model was divided by the maximum value generated by the model with the aim of normalising the response. This ensures a maximum value of F(t)=1 which is required for the calculation of hydraulic parameters and method-of-moments analysis of the residence time distribution. The comparison of this with the conservative tracer regression model response is given in Figure 7.9.

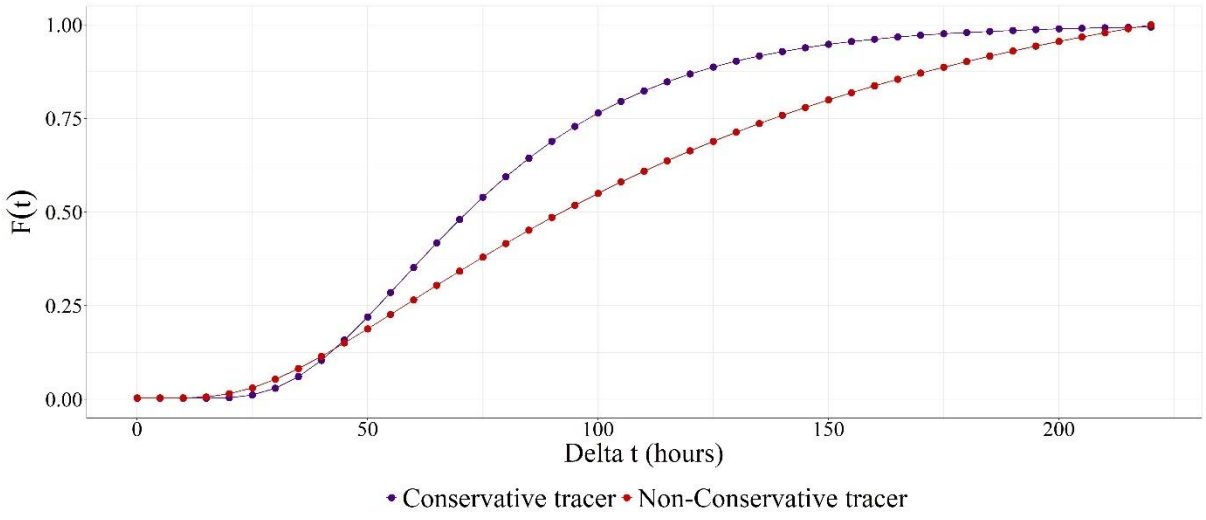

Figure 7.9: *Modeled F(t) response of the conservative tracer, uranine, and the normalised non-conservative tracer, benzoate.*

It can be seen that while the maximum of both is now 1, the shape of the non-conservative tracer response is still different from that of the conservative tracer. This indicates that the effect of either retardation or hydrodynamic dispersion is different and a closer look into these two factors is required.

Mapping 2:

The difference in the two responses given in Figure 7.9 appears to be more of a difference in gradient than a lag in the response, indicating hydrodynamic dispersion (D) would be a better factor to investigate and change. The equation for the hydrodynamic dispersion coefficient is given in Equation 7.12. Hydrodynamic dispersion is a combination of three types of dispersion. Firstly, mechanical dispersion, which can occur in the longitudinal and transversal directions, secondly, molecular dispersion and thirdly macro dispersion. The latter two are often lumped together as one term under the term mechanical dispersion. While the molecular dispersion of the conservative tracer and non-conservative tracer are different, their mechanic dispersions are both a function of sub-surface media and solute and it can be assumed that the mechanical dispersion for two solutes in the same environment would be equal (Equation 7.13) (Marsily, 1986). This leads to the relationship given in Equation 7.14.

$$D = \varepsilon D_m + u[\alpha_l + \alpha_t] \tag{7.12}$$

$$[\alpha_{l,uranine} + \alpha_{t,uranine}] = [\alpha_{l,benzoate} + \alpha_{t,benzoate}] \tag{7.13}$$

$$D_{uranine} = D_{benzoate} - \varepsilon\left[D_{m,benzoate} - D_{m,uranine}\right] \quad (7.14)$$

D_m is the molecular diffusion coefficient of a solute (Marion, 2008). The molecular diffusion coefficient of benzoate is 0.862 x10^{-9} m^2/s (Robinson and Stokes, 1959) and the molecular diffusion coefficient of uranine is 4.5 x 10^{-10} m^2/s (Skagius and Neretnieks, 1986). Using the hydrodynamic dispersion coefficient for benzoate obtained from the regression model (0.020860 m^2/s), the hydrodynamic dispersion coefficient of uranine was calculated to be 0.02086 m^2/s. The molecular diffusion coefficients of the two solutes were too similar to result in a significant difference in the hydrodynamic dispersion coefficients. This is not the same as the hydrodynamic dispersion coefficient of uranine obtained from the regression model, which was approximately 3.5 times lower. The result obtained from solving Equation 7.12 was the basis for keeping the hydrodynamic dispersion coefficient value at 0.020860 m^2/s for the curve-shift technique.

Mapping 3:

From the previous attempt, it was clear that changing the D value was not feasible so some investigation into the retardation factor was done. R is dependent on the distribution coefficient, K_d, which can be defined according to Equation 7.15 (Morrison, 2015b).

$$K_d = f_{om} * K_{om} \quad (7.15)$$

Where f_{om} is the fraction of organic matter in the sub-surface media and K_{om} is the organic matter-water partition coefficient. K_{om} is dependent on K_{ow}, the octanol-water partition coefficient (Berthod and Carda-Broch, 2004). The relationship between K_{om} and K_{ow} for aromatic hydrocarbons is given in Equation 7.16 (Leo *et al.*, 1971). The K_{om} value of uranine is dependent on pH and within the pH range of the experimental setup $\log(K_{om,uranine})$=-0.38 (Oba and Poulson, 2015).

$$log(K_{om}) = 1.01 * log(K_{ow}) - 0.72 \quad (7.16)$$

$\text{Log}(K_{ow,benzoate})$=-2.27(National Center for Biotechnology Information, no date) and from Equation 7.15 it can be determined that $\log(K_{om,benzoate})$=-3.0127. With an assumptions that f_{om}=0.02549 (Cao *et al.*, 2017) the distribution coefficients of benzoate and uranine are determined to be $K_{d,benzoate}$=2.48x10^{-5} and $K_{d,uranine}$=1.06x10^{-2}. This results in the retardation factors of benzoate and uranine to be 1.00 and 1.087 respectively. These theoretical values are

noticeably different from the retardarion factor values obtained from the experimental data. When the theoretical values were used as a constant in the non-linear least squares regression analysis in the comparison of Equation 4.22 and the experimental data, a solution could not be found. This indicates that under these conditions R cannot be equal to 1 for either uranine or benzoate. What can be taken from this is that according to the previous research the retardation factors of benzoate and uranine can be considered similar.

Mapping 4:

From the previous mapping attempts, it is clear that a combination of factors is required to make the curve-shift technique effective. In this set of circumstances it was assumed that the hydrodynamic dispersion factor would be equal to that of benzoate as the rate of dispersion is solute specific and the retardation factor would be equal to that of uranine as it is significantly affected by the sub-surface media. The combination of these two assumptions leads to the comparison response given in Figure 7.10.

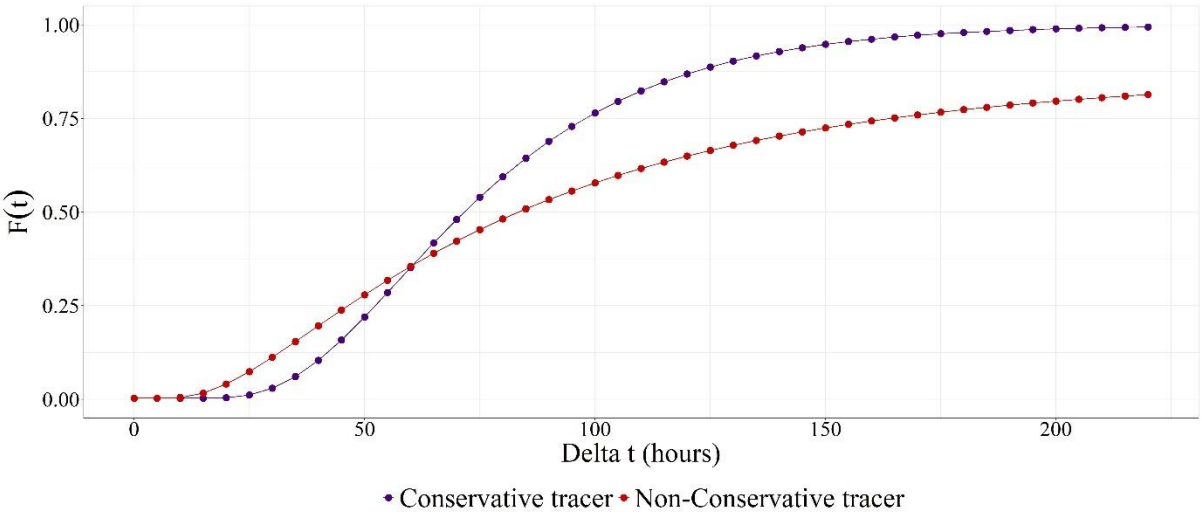

Figure 7.10: *Modeled F(t) response of the conservative tracer, uranine, and the non-conservative tracer, benzoate with R= 3.550119 and D= 0.020860*

These two values were used and then the final values were normalised and this resulted in the response given in Figure 7.11.

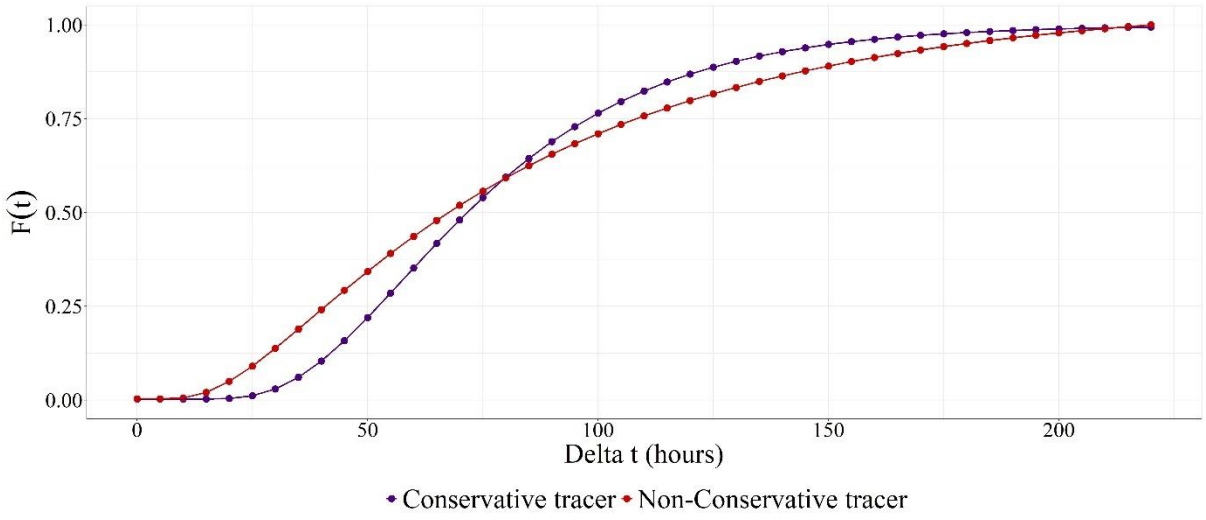

***Figure 7.11**. Modeled F(t) response of the conservative tracer, uranine, and the non-conservative tracer, benzoate with R= 3.550119 and D= 0.020860 and normalised to the maximum of the benzoate model output.*

The hydraulic parameters for interpreting the RTD obtained from the non-conservative response given in Figure 7.10 are indicated in Table 7.8. The correlation coefficient between the mapped response and the tracer model is 0.9922.

***Table 7.8:** Hydraulic performance indices of the mapped non-conservative tracer response*

Parameter	Value
t_m (hours)	79.47 hours
N	2.64
e	1.10
λ	0.687
σ^2	2385.44

The code used to generate Figure 7.9, Figure 7.10 and Figure 7.11 and determine the hydraulic parameters of each mapped response can be found in Appendix L and Appendix M.

7.3.4 Discussion

From the four mapping exercises conducted here, it is clear that attempt 4 was the most accurate in correlating the normalized response curves. The hydraulic parameters calculated from the mapped response of the non-conservative tracer are similar to those of the conservative tracer.

The mean residence time from the regression model of the conservative tracer was 78.99 hours and the mean residence time from the mapping technique is within 0.61% of that, at 79.47 hours. The mean residence time is the most commonly used of the hydraulic parameters, especially in reactor design models (Levenspiel, 1999). It is important for design purposes that an accurate mean residence time is determined as this is the primary sizing parameter

(Zahraeifard and Deng, 2011). A difference of 0.61 % is low enough to be considered negligible and the mean residence time obtained from the mapped non-conservative tracer response curve can be used.

The number of tanks in series calculated from the regression model of the conservative tracer is 4.63 but the number of tanks in series calculated from the mapped non-conservative tracer response is 2.64. This indicates that the mapped non-conservative tracer displays more back mixing in the system than the conservative tracer. This may be due to benzoate, the non-conservative tracer, diffusing faster as it has a smaller molecular weight. This behaviour is also seen in the response curves given in Figure 7.11. It can be seen that the gradient of the conservative tracer is steeper than that of the non-conservative tracer which means that the latter has a greater diffusion, resulting in more mixing and a smaller N than the conservative tracer. The number of tanks in series is dependent on wetland configuration, aspect ratio, the presence of baffles and the location and density of plants. The values obtained in this study are within the range expected for a horizontal sub-surface flow constructed wetland. As the flow paths of the wetland all converge at one outlet point a high degree of back mixing is expected (Bonner *et al.*, 2017).

The effective volume ratio of the conservative response and of the mapped non-conservative response are 1.09 and 1.10, respectively. These are similar and both greater than 1. These effectve volume ratios are higher than the values obtained in some other studies (Suliman, Futsaether, *et al.*, 2006; Sheridan, Hildebrandt and Glasser, 2013; Sheridan, Glasser and Hildebrandt, 2014) but was in line with the effective volume ratio determined by Bonner et al. (2017). The effective volume ratio of a system is affected by the inlet-outlet set-up as well as the wetland configuration (Sabokrouhiyeh *et al.*, 2017). Sheridan (2012) found that when the inlet and the outlet port were close to the surface of the wetland the flow of the water followed a hull shape (Sheridan, 2012). The inlet port of the wetland in this study is at the surface of the gravel while the outlet port is close to the base of the wetland. It is likely that this configuration prevented the hull type fluid flow from forming and the flow was more likely to follow a hysterisis shape resulting in a smaller dead volume and higher effective volume ratio.

There was a substantial difference in the hydraulic efficiencies obtained from the regression model of the conservative tracer (0.86) and the mapped response of the non-conservative tracer (0.68). Since hydraulic efficiency is a function of N, and the difference in N was noted previously, this difference in hydraulic efficiency is expected. Hydraulic efficiency is a

function of the design of a system; its aspect ratio, the presence and location of baffles and the location of islands in a system (Persson, 2000). The hydraulic efficiency values obtained in this study are inline with what is expected for a wetland of this setup.

The technique developed here was based on experiments conducted in a small horizontal sub-surface flow constructed wetland and using the advective-dispersive solute transport equation. It can be applied in larger and outdoor systems as long as the flow through the wetland is laminar. As for most tracer studies all possible outlets of the wetland should be monitored and samples should be taken for tracer concentration to ensure that stead-state has been reached. Steady flow is also an important factor for this technique to be applied.

7.4: Conclusion

The calibration of two novel residence time distribution techniques was given in this Chapter. The first technique was based on the method-of-moments technique which is used to investigate and describe the residence time distribution of a reactive system. This technique was calibrated on two systems; a set of gravel filled columns and a small-scale CW. Two systems were used as they have different factors which contribute to non-ideal flow, with the CW being more intricate. To display the adapted method-of-moments technique the area under the residence time distribution curve was divided into 5 sections, each with equal volume. It is possible to divide the area under the curve into any number of sections. An increase in the number of sections means more in-depth analysis but increased time and computational power. The sections can also be divided into equal time periods, rather than equal areas. The limitation of this techniques lies in the use of first-order reaction rates, which are required for the technique in the current form.

The second technique which was calibrated in this chapter was the curve-shift technique. A methodology by which it is possible to use a non-conservative tracer (such as benzoate or any other compound which is likely to be degraded) to determine the flow characteristics of a HSSF CW. It can be applied in larger and outdoor systems as long as the flow through the wetland is laminar. As for most tracer studies all possible outlets of the wetland should be monitored and samples taken for tracer concentration to ensure that stead-state has been reached. Steady flow is also an important factor for this technique to be applied.

The technique was found to accurately predict the mean residence time of the systems studied. This allows the researcher to consider the use of biodegradable tracers for conducting step-change tracer studies. This has the potential to reduce the environmental impact of research without compromising the integrity of the data gathered. Caution is necessary when using this method – the data obtained from the other moments of the distribution (such as dispersion, retardation, etc.) are not as well quantified. If these are important, they must be given due consideration. There is also considerable scope for this technique to be expanded to other reactor systems such as general chemical or biochemical engineering. Examples include those instances where heat may decompose the tracer, or where the tracer reacts (as opposed to biodegrades) within the reactor itself. The method would most likely need to be adapted somewhat for those circumstances. Further studies on this technique could also be considered to determine the effect of other parameters such as aspect ratio, particle size, the proximity of the Reynold's number to turbulent flow, etc. It is also recommended that more frequent sampling is done than was given in this study to ensure accurate model predictions. It is important for environmental research (and indeed, any research) not to aggravate environmental degradation. This study contributes towards achieving this goal.

Chapter 8: Discussion and concluding remarks.

8.1: Discussion

This chapter provides a summary of the findings of this thesis and relates these findings to the research objectives discussed in Section 2.11.

Objective 1: Develop a novel residence time distribution technique in order to improve the accuracy and the measurement and quantification of CW hydraulic flow behaviour.

The first objective was to develop a novel residence time distribution technique which could be used to quantify the hydraulics of a constructed wetland. The principal goal of this objective was to develop a different way of representing the hydraulic behaviour of a constructed wetland which had some flexibility so that it could be used for design without being computationally intensive but would also allow the researcher to analyse the hydraulic behaviour in detail. Two techniques were developed to address this. The results are summarised below.

Two novel residence time distribution techniques were developed. The first technique was based on the method-of-moments technique for the analysis of data from residence time distribution studies. This technique assumed that there were multiple flow velocity pathways along the length of a constructed wetland and within each flow path there were micro-batch reactors. The theory was that these micro-batch reactors would spend different amounts of time in the system, owing to their different flow paths, and as a result there would be a variation in the reaction time of each of the micro-batch reactors and therefore the pollutants in the water. Each of these flow paths was represented as portion of area under the residence time distribution curve. The fraction of area which represented a specific flow path also determined the percentage of the volume of fluid which the flow path took up in the system. The mean residence time for each portion was be determined and represented in a vector. Because of the assumption of micro-batch reactors, the batch reactor design equation was used, along with first-order rate laws, to determine the pollutant removal of each of the flow paths. The degradation achieved in each flow path was added together to determine the overall degradation of the system. The benefit of the technique presented was that it allowed the user to determine the level of complexity required for their modelling needs by varying the number of flow paths

assumed in the reactor. The decision to divide the system into additional flows paths would require additional computation but would allow for better understanding of pollutant removal and a better analysis of the hydraulic behaviour of the constructed wetlands. The decision to divide the system into fewer paths would mean that the technique is computationally simple but would not necessarily permit an in-depth analysis.

The second technique developed was based on improving the modelling of constructed wetlands from the perspective of environmental impact. For a tracer to accurately describe the flow of water through a constructed wetland, it must not undergo adsorption, biodegradation, or photodegradation. However, these properties of the tracer also mean that it can pose an environmental problem (since those properties are the same as for persistent pollutants) and hence requires correct disposal. Because of this, the use of a non-conservative tracer was investigated. A non-conservative tracer gives a distorted response curve to residence time distribution studies and an understanding of solute transport was required to counter these distortions and relate the non-conservative response to a conservative response This technique was based on the advective-dispersive transport equation, which is used for the transport of a solute through a packed bed in which the solute may degrade. Analytical solutions for the transport equation, with and without decay, were determined. These analytical solutions were used to predict the response curve of a step-change tracer study. An understanding of hydrodynamic dispersion, retardation, and decay was used to shift the response curve of the non-conservative tracer to that of the conservative tracer. From the shifted curve, hydraulic parameters were determined.

Both techniques developed were able to quantify the hydraulic flow behaviour of a constructed wetland. The adapted method-of-moments technique was developed for first-order reaction rate laws and this limits its use currently. However, the development of the technique using rate laws of higher order is recommended for future work. The technique is simple to use and does not require an advanced knowledge of numerical modelling methods or a specific software. The curve-shift technique which was developed was successful in correlating the parameters which affect solute transport and using these parameters to relate the response curve of a conservative and non-conservative tracer. The limitation of this technique is that the advective-dispersive transport equation can only be used for HSSF CWs and therefore is not applicable for all wetland types. It is recommended that further work be done to determine whether a similar technique can be applied on other solute transport equations.

Objective 2: Apply the novel residence time distribution technique to an existing biokinetic model, the International Water Association's constructed wetland model 1 (CWM1), to improve the accuracy of the predicted output concentrations of contaminants.

The second objective of this study was to apply the novel residence time distribution techniques to a biokinetic model; specifically, the Constructed Wetland Model No1. To achieve this objective for the first technique, the two matrices of CWM1 were used. The first matrix contained the reaction rates of the seventeen processes which are modelled in CWM1 and the other contained the stochiometric coefficients which related each of the processes to sixteen components. A dot product of these two matrices produced a matrix in which the transformation of component 'i' in process 'l' was in row *'i'*, column *'l'* of the matrix. For this matrix to be used with the adapted method-of-moments technique, each of the rates was assumed to be first order. This was achieved through linearisation techniques.

It was simpler to combine a biokinetic model with a curve-shift technique. The advective-dispersive transport equation is a partial differential equation which can be solved with other differential equations to describe the flow and degradation of solutes. The use of CWM1 with the curve-shift technique was be achieved in the same way as the biokinetic model has been used with the original advective-dispersive transport equation using partial differential equations.

Objective 3: To modify the matrices of stochiometric coefficients and rate laws given in CWM1 to include a residence time distribution function.

The third objective of this thesis was to modify the matrices of CWM1 to include a residence time distribution function. In the case of the curve-shift technique, this was not necessary since the hydraulic and biokinetic models could be used together in their original forms. However, in the case of the adapted method-of-moments technique, for the biokinetic model and the hydraulic technique to be combined, the reaction rates needed to be first order. This meant that the rate at which component *'i'* was degraded in process *'l'* needed to be linearised. It was assumed that at an instantaneous moment in time, all concentrations and parameters which affected the degradation of component *'i'* were constant, except for the concentration of component *'i'*. This meant that the relationship between component *'i'* and the rate at which it was degraded/produced in process *'l'* could be determine and linearised. Two methods were used to attempt this: Taylor series approximations and McLaurin series approximations. Padé

approximations were also considered but since the first order Padé approximation was mathematically equivalent to the first order Taylor series approximation around the same point, the Padé approximants were not investigated further.

Linearisation of 29 component reaction rate equations in total was attempted. There were cases where the Taylor series approximation and the McLaurin series approximation displayed the same behaviour for multiple rates of transformation of the same component. In these cases, only one transformation rate was discussed in detail. A summary of the components on which linearisation was attempted is given below.

- Dissolved oxygen (S_O): Four processes were modelled for the transformation of dissolved oxygen. In all four cases the relationship between the concentration of dissolved oxygen and the rate it was degraded in process *'l'* was not linear. Even at low concentrations the McLaurin series approximation deviated from the rate determined using the CWM1. At the basis concentration the McLaurin series approximation of transformation rate was 5.3 times greater in magnitude than the original, for three cases, and 1.86 times greater in magnitude for the fourth case. The McLaurin series was not a good approximation for any of the cases of dissolved oxygen. Within a small concentration range of 0.43 mg O_2/L to 1.30 mg O_2/L, the Taylor series approximation was a good representation of the rate determined using the CWM1, but outside of that range the approximation deviated. As very low concentrations of dissolved oxygen are common in constructed wetlands, the deviation at concentrations below 0.43 mg O_2/L of the Taylor series approximation meant that this technique could not be used to linearise the reaction rates of dissolved oxygen.
- Fermentable, readily biodegradable COD (S_F): Three processes were modelled for COD. In all three cases, the higher the concentration of COD the faster it is degraded in the process, but there came a point at which the rate of transformation was not limited by the concentration of COD but by the rate at which the bacteria could degrade COD. The McLaurin series approximation deviated from the original rate at very low concentrations and at the basis concentration was 692 times greater in magnitude than the rate determined using the CWM1, for two cases, and 7.07 times greater in magnitude for the other. The McLaurin series was not a good approximation for any of the rates of transformation of COD. The Taylor series approximation was in the same order of magnitude as the rate determined using the CWM1 but did not display the same

behaviour around the basis concentration or within the given range. This means that neither the Taylor series approximation nor the McLaurin series approximation were suitable to be used for the linearisation of the rates of COD.

- Fermentation products, as acetate, (S_A): Four processes were modelled for the transformation of acetate. Two of these processes, the anoxic growth of heterotrophic bacteria on acetate and COD, displayed the same behaviour. The Taylor series approximation for these two processes deviated from the original rate, above and below the basis concentration, and was not a good estimate of the rate determined using the CWM1. The McLaurin series approximation of these two rates displayed similar behaviour within the given concentration range and the root mean square error for the anoxic growth of heterotrophic bacteria on acetate and COD was 0.3 mg COD/L.d and 0.363 mg COD/L.d, respectively. In these two cases the linearisation of the reaction rates was achieved. For the other two processes which were modelled for acetate, the Taylor series approximation overestimated the rate on both sides of the basis concentration. The McLaurin series approximation deviated from the original rate at concentrations greater than 0 mg COD/L. At the basis concentration the McLaurin series approximation was 1.48 and 2.13 times greater than the original rate for the growth of acetotrophic, methanogenic bacteria and growth of acetotrophic, sulphate reducing bacteria, respectively.
- Ammonium and ammonia nitrogen (S_{NH}): Ten processes were modelled for the transformation of ammonium. They all displayed the same behaviour in terms of the rate determined using the CWM1, Taylor series approximation and McLaurin series approximation. The relationship between the concentration of ammonium and the rate at which it is degraded in the growth of heterotrophic bacteria on COD was exponential and as the concentration of ammonium increased, the rate at which it was transformed also increased but began to flatten out at approximately 10 mg N/L. There came a point at which the process was limited not by the concentration of ammonium, but by the rate at which bacteria could transform ammonium. At the basis concentration, the McLaurin series approximation of rate was 1141 times larger in magnitude than the rate determined using the CWM1 for six processes, 5701 times larger for three processes and 114 times larger for one process. The Taylor series approximation was a good estimate of the rate determined using the CWM1 within the range that the original rate flattened out. The McLaurin series approximation cannot be used for the linearisation

of ammonium but there are ranges in which the Taylor series approximation could be used.

- Nitrate and nitrite nitrogen (S_{NO}): Three processes were modelled for nitrate and all of them displayed similar behaviour for the rate determined using the CWM1, the Taylor series approximation and the McLaurin series approximation. Each of the rates displayed an exponential behaviour and flattened out at a relatively low concentration. The McLaurin series approximation had a much steeper gradient than the flattened-out section of the rate determined using the CWM1. At the basis concentration the McLaurin series approximation was 101.8 times greater than the original rate for all three processes modelled. The Taylor series approximation displayed a similar behaviour to the rate determined using the CWM1 over a small range but at concentrations of less than 25 mg N/L, the two displayed different behaviour. Neither the McLaurin series nor the Taylor series approximation were a good enough linear estimation of the rate determined using the CWM1 for nitrate.
- Sulphate sulphur (S_{SO4}): One process was modelled for sulphate. The relationship between the concentration of sulphate and the rate at which it was transformed in the growth of acetotrophic, sulphate reducing bacteria was not linear. The McLaurin series approximation deviated from the original rate at concentrations greater than 0 mg S/L. At the basis concentration, the McLaurin series approximation was 2.84 times greater than the rate determined using the CWM1. The Taylor series approximation was only a good estimate of the rate determined using the CWM1 at the basis concentration, on either side of this the behaviour of the approximation was very different from that of the rate determined using the CWM1 This means that neither the Taylor series nor the McLaurin series approximation can be used to linearise the rate at which sulphate is degraded in the growth of acetotrophic, sulphate reducing bacteria.
- Dihydrogen-sulphide sulphur (S_{H2S}): Three processes were modelled for the rate at which dihydrogen sulphide is transformed. The relationship between the rate at which dihydrogen-sulphide was transformed in the growth of acetotrophic, sulphate reducing bacteria and the concentration of dihydrogen-sulphide displayed different behaviour to the other two rates. The rate was not exponential and within the given range was close to a linear rate. The McLaurin series approximation deviated more from the rate determined using the CWM1 as the concentration of dihydrogen-sulphide increased. At the basis concentration, the McLaurin series approximation was 1.25 times greater than

the rate determined using the CWM1. The Taylor series approximation was greater than the rate determined using the CWM1 for the full concentration range, except at the basis concentration, at which points the rates were equal. Neither the McLaurin series nor the Taylor series approximation was a good estimation of the rate determined using the CWM1 for this process. The other two processes displayed a different type of behaviour. The relationship between the concentration of dihydrogen-sulphide and the rate at which it was consumed in the aerobic growth of sulphide oxidising bacteria on dihydrogen-sulphide and anoxic growth of sulphide oxidising bacteria on dihydrogen sulphide was exponential and as the concentration of dihydrogen-sulphide increases, the rate at which it was degraded in these two processes increased in magnitude, before flattening out at a concentration of approximately10 mg S/L. The McLaurin series approximation deviated from the rate determined using the CWM1 above a concentration of 0 mg S/L. At the basis concentration the magnitude of the McLaurin series approximation was 143 times greater than the rate determined using the CWM1 for both processes. Within a small range the Taylor series approximation displayed the same behaviour as the rate determined using the CWM1. However, at concentrations lower than 10 mg S/L the deviation increased. The Taylor series approximation could give a linear approximation of the rate determined using the CWM1 within a small concentration range for both in the aerobic growth of sulphide oxidising bacteria on dihydrogen-sulphide and anoxic growth of sulphide oxidising bacteria on dihydrogen-sulphide.

- Slowly biodegradable particulate COD (X_S): One process was modelled for particulate COD. The relationship between concentration of particulate COD and rate at which it was transformed was not linear but neither did it flatten out like the behaviour seen for some of the other components. The McLaurin series deviated from the rate determined using the CWM1 at concentrations greater than 0 mg O_2/L and at the basis concentration the McLaurin series approximation was 2.65 times greater in magnitude than the original rate. The Taylor series approximation estimated a rate of greater magnitude than the original rate at every point except the basis concentration. Neither the McLaurin series nor the Taylor series approximation were a good linear estimation of the rate.

Of the twenty-nine rates for which linear approximation techniques were attempted, only two were successful. These two were the rate at which acetate was degraded in the anoxic growth

of heterotrophic bacteria on acetate and fermentable, readily biodegradable COD and these two displayed the same behaviour. For nineteen of the other rates there was a limited range in which the Taylor series approximation had some accuracy, but not enough to describe the full degradation of the components. There was no success for the linearisation of the remaining eight rates.

Because of the limited success in linearising the rates at which specific components were degraded/produced in specific processes, the CWM1 matrix was not modified to include the residence time distribution function of the adapted method-of-moments technique. Further investigation needs to be done into the use of stepwise linearisation of the rates. Another avenue worth investigating is the use rate laws of higher powers. This will involve changing the adapted method-of-moments technique but may yield more success than linearisation.

Objective 4: To calibrate the model on a small-scale indoor reactor

The fourth objective of this thesis was to calibrate the two techniques on a simple, indoor, HSSF CW reactor. To achieve this, different tracer studies were conducted. Three sets of tracer studies were conducted, two for the adapted method-of-moments technique and one for the curve shift technique. The first set of tracer tests conducted were impulse-response tracer studies and these were conducted on three vertical flow columns. This set of tests was done to calibrate the adapted method-of-moments technique.

- An impulse-response tracer study was conducted on three vertical flow columns.
- The peak of the residence time distribution curve arrived after 40 minutes and there was a long, drawn-out tail. This tail was expected for flow though gravel systems.
- The mean residence time of the system was 80.9 minutes, which was very close to the nominal residence time of 79 minutes and the number of tanks in series was 90. This indicated a large amount of micro-mixing in the system.
- The mean residence time of the system and the nominal residence time were only 1.9 minutes apart and this could lead to the assumption that the system behaves in an ideal manner. But by dividing the area under the curve into portions it is possible to analyse the response in more detail and identify non-ideal flow behaviour, and hence more accurate modelling.
- The area under the curve was divided into five portions, each represented a flow path through the system. Each portion of area was approximately 20% of the total area and

therefore each portion represented approximately 20% of the fluid flowing through the system.

- The mean residence time for portions 1, 2, 3, 4 and 5 were 31.00 minutes, 45.85 minutes, 61.05 minutes, 89.15 minutes, and 177.70 minutes, respectively. Three out of the five portions had a mean residence time greater than the nominal residence time determined for the portion and two had a mean residence time less than the nominal residence time determined for the portion.
- The time period over which each of the portions was distributed is different. This indicates that the mixing is not evenly distributed. As the last portion takes place over the largest time period, it can be said that the effect of mixing was greatest in this portion.
- The data from the experiments were successfully used in the adapted method-of-moments technique with a theoretical kinetic model.
- A comparison between the outlet concentration of a theoretical component using the nominal residence time and mean residence time of each portion was presented and by using the mean residence time more degradation was prediccted.

The second set of impulse-response tracer tests were conducted on a small scale HSSF constructed wetland. This was done to validate the adapted method-of-moments technique on a system more complex than the vertical flow columns.

- The mean residence time of the system was 6.67 hours, which is 2 hours longer than the nominal residence time of the system. This indicated that the water took longer to get through the system than expected.
- Instead of one peak which was seen in the first experiment, there were four peaks in this experiment, coming through at 4.4 hours, 4.75 hours, 6.5 hours, and 7.55 hours. These peaks indicated multiple and semi-distinct flow paths through the wetland and are the cause of the large mean of the residence time distribution.
- The number of tanks-in-series for this system was 7.9. which indicates that while there were multiple flow paths in the system, there was minimal mixing.
- There area under the curve was divided into five portions, each representing a flow path through the system. Each portion of area was approximately 20% of the total area and therefore each portion represented approximately 20% of the fluid flowing through the system.

- The mean residence time for portions 1, 2, 3, 4 and 5 were 3.9 hours, 5.14 hours, 6.25 hours, 7.86 hours, and 10.49 hours, respectively. Three out of the five portions had a mean residence time greater than the nominal residence time determined for the portion and two had a mean residence time less than the nominal residence time determined for the portion. However, the mean residence time and the nominal residence time were not significantly different for all 5.
- The time period over which each of the portions was distributed is different. This indicates that the mixing is not evenly distributed. As the last portion takes place over the largest time period, it can be said that the effect of mixing was greatest in this portion.
- The data from the experiments were used in the adapted method-of-moments technique with a theoretical kinetic model.
- A comparison between the outlet concentration of a theoretical component using the nominal residence time and mean residence time of each portion was presented and by using the mean residence time less degradation was precited. However, as the nominal and mean residence times for each of the sections was so similar the predicted outlet concentrations were also similar.

The third tracer study conducted was a step-change tracer study and this was conducted on a small scale HSSF constructed wetland to validate the curve-shift technique. A non-linear least-squares regression analysis was used to fit the data from the step-change tracer study to an analytically solved form of the advective-dispersive transport equation. The transport equation, without decay, was used for the conservative tracer uranine, and the transport equation with decay was used for the non-conservative tracer, benzoate. The solved advective-dispersive transport equation, with and without decay, was fitted to the benzoate and uranine step-changes response curves, respectively. The fitted curve was used to determine the retardation factor and dispersion coefficient of each of the tracers. A summary of the main findings is given below:

- Four curve-shift techniques were attempted. The first was a normalization of the non-conservative tracer response curve, to make the maximum 1. However, the shape of the non-conservative tracer response curve and the conservative tracer response curve was still different and therefore the hydraulic parameters determined from the non-conservative response curve would be inaccurate.

- The second attempt was to investigate and draw correlations between the hydrodynamic dispersion of each of the tracers, but the investigation showed them to be similar and the dispersion coefficient of the non-conservative tracer was kept as its original value.
- The third technique tried was to investigate a retardation factor, which is a function of the distribution coefficient. The research suggested that the retardation factor for both tracers was equal to 1, however, at this value, the non-linear least-squares regression analysis was not able to find a solution and therefore this cannot be true for either of these tracers. The retardation factors were kept at their original values.
- In the fourth attempt the hydrodynamic dispersion coefficient of benzoate and the retardation factor of uranine was chosen. The results from this were then normalised and this yielded a response curve for the non-conservative tracer which was similar to that of the conservative tracer.
- Hydraulic parameters from each of the responses were compared.
- The technique was found to most accurately predict the mean residence time. Caution is necessary when using this method – the data obtained from the other moments of the distribution (such as dispersion, retardation, etc.) are not as well quantified. If these are important, they must be given due consideration.

Through the conduction of the three tracer studies, two impulse-response and one step change calibration of the two techniques was achieved. It is possible to use the data from the impulse-response tracer studies in the adapted method-of-moments techniques to investigate the non-ideal flow behaviour of constructed wetlands. Work needs to be done to combine the adapted method-of-moments technique with an existing kinetic model. The curve shift technique was successful is estimating hydraulic parameters of a HSSF CW. It is suggested that future work be conducted to determine the applicability of the technique with other non-conservative tracers.

Objective 5: To validate the model on a large-scale outdoor established wetland.

The fifth objective was to validate the techniques on a large scale outdoor established wetland. This was not possible since access to a large-scale outdoor CW could not be granted. The proposed CW was in Leipzig, at the Helmholtz UFZ. The Covid-19 pandemic has precluded international travel and thus, this objective was not achieved. It is suggested that this objective form the basis of future work.

8.2 Concluding remarks

Modelling the hydraulic behaviour of constructed wetlands is not simple and to gain an understanding of the behaviour, residence time distribution studies are required. These are an inexpensive and easy way to investigate the extent of non-ideal behaviour and give an indication of how the system should be modelled. Various methods exist which can be used to model the behaviour of constructed wetlands and these are based either on data from residence time distribution studies or simulations. These methods range from the simple use of a nominal residence time value, which assumes ideal plug flow, to partial differential equations describing advective and dispersive transport in multiple directions.

Two novel residence time distribution techniques were presented in this thesis. The first is a technique based on the method-of-moments technique used for interpreting data from residence time distribution studies. The adapted technique allows the researcher to divide the area under a residence time distribution curve into multiple portions. The number of portions chosen is dependent on the computation power and time available to the researcher. The aim of this technique is to be used with a biokinetic model, such as CWM1, and in the current format the technique requires the reactions rates of the biokinetic model to be first order. While the linearisation of the reaction rates of CWM1 was not achieved, the applicability of the technique in interpreting residence time distribution data was displayed. This was done for a set of simple gravel columns and a horizontal sub-surface flow constructed wetland. The limitation of the technique lies in the need for the reaction rates to be in a format which can undergo differentiation and result in a relatively simple answer.

The second technique which was presented in this thesis was a curve-shift technique in which the response curve of a non-conservative tracer was mapped to that of a conservative tracer. The technique was found to most accurately predict the mean residence time. This allows the researcher to consider the use of biodegradable tracers for conducting step-change tracer studies and in doing so reduce the environmental impact of research without compromising the integrity of the data gathered. Caution is necessary when using this method – the data obtained from the other moments of the distribution (such as dispersion, retardation, etc.) are not as well quantified. If these are important, they must be given due consideration.

Further work is recommended for both the adapted method-of-moments technique and then the curve shift technique. Further investigations into the use of the adapted method-of-moments

technique on other wetland systems, such a vertical flow constructed wetland or free water surface constructed wetlands is suggested. The use of higher order rate laws is recommended, such as second and third order, which can be analytically differentiated. This will allow for the use of more kinetic rate equations. There is also considerable scope for the curve shift technique to be expanded to other reactor systems such as general chemical or biochemical engineering. Examples include those instances where heat may decompose the tracer, or where the tracer reacts (as opposed to biodegrades) within the reactor itself. The method would most likely need to be adapted somewhat for those circumstances. Further studies on this technique could also be considered to determine the effect of other parameters such as aspect ratio, particle size, the proximity of the Reynold's number to turbulent flow, etc. It is important for environmental research (and indeed, any research) not to aggravate environmental degradation. This study contributes towards this goal.

Appendix B

Constants for the simplified rates presented in Chapter 6.

Dissolved oxygen

Process 2:

$$P_{2,1} = \left[1 - \frac{1}{Y_H}\right] * \mu_H * \left[\frac{S_F}{K_{SF} + S_F}\right] * \left[\frac{S_F}{S_F + S_A}\right] * \left[\frac{S_{NH}}{K_{NHH} + S_{NH}}\right] * \left[\frac{K_{H2SH}}{K_{H2SH} + S_{H2S^*}}\right] * X_H$$

$$Q_{2,1} = K_{OH}$$

Process 4:

$$P_{4,1} = \left[1 - \frac{1}{Y_H}\right] * \mu_H * \left[\frac{S_A}{K_{SA} + S_A}\right] * \left[\frac{S_A}{S_F + S_A}\right] * \left[\frac{S_{NH}}{K_{NHH} + S_{NH}}\right] * \left[\frac{K_{H2SH}}{K_{H2SH} + S_{H2S^*}}\right] * X_H$$

$$Q_{4,1} = K_{OH}$$

Process 7:

$$P_{7,1} = \left[-\frac{4.57 - Y_A}{Y_A}\right] * \mu_A * \left[\frac{S_{NH}}{K_{NHA} + S_{NH}}\right] * \left[\frac{K_{H2SA}}{K_{H2SA} + S_{H2S^*}}\right] * X_A$$

$$Q_{7,1} = K_{OA}$$

Process 15:

$$P_{15,1} = \left[-\frac{2 - Y_{SOB}}{Y_{SOB}}\right] * \mu_{SOB} * \left[\frac{S_{H2S}}{K_{SSOB} + S_{H2S}}\right] * \left[\frac{S_{NH}}{K_{NHSOB} + S_{NH}}\right] * X_{SOB}$$

$$Q_{15,1} = K_{OSOB}$$

Fermentable, readily biodegradable COD

Process 1:

$$P_{1,2} = \left[1 - \mathrm{f_{Hyd,SI}}\right] * k_h * \left[\frac{\frac{X_s}{X_H + X_{FB}}}{K_X + \frac{X_s}{X_H + X_{FB}}}\right] * \left(X_H + \eta_h * X_{FB}\right)$$

Process 2:

$$P_{2,2} = \left[-\frac{1}{Y_H}\right] * \mu_H * \left[\frac{S_O}{K_{OH} + S_O}\right] * \left[\frac{S_{NH}}{K_{NHH} + S_{NH}}\right] * \left[\frac{K_{H2SH}}{K_{H2SH} + S_{H2S^*}}\right] * X_H$$

$$Q_{2,2} = K_{SF}$$

$$R_{2,2} = S_A$$

Process 3:

$$P_{3,2} = \left[-\frac{1}{Y_H}\right] * n_g * \mu_H * \left[\frac{K_{OH}}{K_{OH} + S_O}\right] * \left[\frac{S_{NO}}{K_{NOH} + S_{NO}}\right] * \left[\frac{S_{NH}}{K_{NHH} + S_{NH}}\right] * \left[\frac{K_{H2SH}}{K_{H2SH} + S_{H2S^*}}\right] * X_H$$

$$Q_{3,2} = K_{SF}$$

$$R_{3,2} = S_A$$

Process 6:

$$P_{6,2} = f_{BM,SF} * b_H * X_H$$

Process 8:

$$P_{8,2} = f_{BM,SF} * b_A * X_A$$

Process 9:

$$P_{6,2} = \left[-\frac{1}{Y_{FB}}\right] * \mu_{FB} * \left[\frac{K_{H2SFB}}{K_{H2SFB} + S_{H2S^*}}\right] * \left[\frac{K_{OFB}}{K_{OFB} + S_O}\right] * \left[\frac{K_{NOFB}}{K_{NOFB} + S_{NO}}\right] * \left[\frac{S_{NH}}{K_{NHFB} + S_{NH}}\right] * X_{FB}$$

$$Q_{9,2} = K_{SFB}$$

Process 10:

$$P_{10,2} = f_{BM,SF} * \ b_{FB} * X_{FB}$$

Process 12:

$$P_{12,2} = f_{BM,SF} * b_{AMB} * X_{AMB}$$

Process 14:

$$P_{14,2} = f_{BM,SF} * b_{ASRB} * X_{ASRB}$$

Process 17:

$$P_{17,2} = f_{BM,SF} * b_{SOB} * X_{SOB}$$

Fermentation products as acetate

Process 4:

$$P_{4,3} = \left[-\frac{1}{Y_H}\right] * \mu_H * \left[\frac{S_O}{K_{OH} + S_O}\right] * \left[\frac{S_{NH}}{K_{NHH} + S_{NH}}\right] * \left[\frac{K_{H2SH}}{K_{H2SH} + S_{H2S^*}}\right] * X_H$$

$$Q_{4,3} = K_{SA}$$

$$R_{4,3} = S_F$$

Process 5:

$$P_{5,3} = \left[-\frac{1}{Y_H}\right] * n_g * \mu_H * \left[\frac{K_{OH}}{K_{OH} + S_O}\right] * \left[\frac{S_{NO}}{K_{NOH} + S_{NO}}\right] * \left[\frac{S_{NH}}{K_{NHH} + S_{NH}}\right] * \left[\frac{K_{H2SH}}{K_{H2SH} + S_{H2S^*}}\right] * X_H$$

$$Q_{5,3} = K_{SA}$$

$$R_{5,3} = S_F$$

Process 9:

$$P_{9,3} = \left[\frac{1 - Y_{FB}}{Y_{FB}}\right] * \mu_{FB} * \left[\frac{S_F}{K_{SFB} + S_F}\right] * \left[\frac{K_{H2SFB}}{K_{H2SFB} + S_{H2S^*}}\right] * \left[\frac{K_{OFB}}{K_{OFB} + S_O}\right] * \left[\frac{K_{NOFB}}{K_{NOFB} + S_{NO}}\right] * \left[\frac{S_{NH}}{K_{NHFB} + S_{NH}}\right] * X_{FB}$$

Process 11:

Process 14:

$$P_{14,9} = f_{BM,XI} * b_{ASRB} * X_{ASRB}$$

Process 17:

$$P_{17,9} = f_{BM,XI} * b_{SOB} * X_{SOB}$$

Heterotrophic bacteria

Process 2:

$$P_{2,11} = \mu_H * \left[\frac{S_F}{K_{SF} + S_F}\right] * \left[\frac{S_F}{S_F + S_A}\right] * \left[\frac{S_O}{K_{OH} + S_O}\right] * \left[\frac{S_{NH}}{K_{NHH} + S_{NH}}\right] * \left[\frac{K_{H2SH}}{K_{H2SH} + S_{H2S^*}}\right]$$

Process 3:

$$P_{3,11} = n_g * \mu_H * \left[\frac{S_F}{K_{SF} + S_F}\right] * \left[\frac{S_F}{S_F + S_A}\right] * \left[\frac{K_{OH}}{K_{OH} + S_O}\right] * \left[\frac{S_{NO}}{K_{NOH} + S_{NO}}\right] * \left[\frac{S_{NH}}{K_{NHH} + S_{NH}}\right] * \left[\frac{K_{H2SH}}{K_{H2SH} + S_{H2S^*}}\right]$$

Process 4:

$$P_{4,11} = \mu_H * \left[\frac{S_A}{K_{SA} + S_A}\right] * \left[\frac{S_A}{S_F + S_A}\right] * \left[\frac{S_O}{K_{OH} + S_O}\right] * \left[\frac{S_{NH}}{K_{NHH} + S_{NH}}\right] * \left[\frac{K_{H2SH}}{K_{H2SH} + S_{H2S^*}}\right]$$

Process 5:

$$P_{5,11} = n_g * \mu_H * \left[\frac{S_A}{K_{SA} + S_A}\right] * \left[\frac{S_A}{S_F + S_A}\right] * \left[\frac{K_{OH}}{K_{OH} + S_O}\right] * \left[\frac{S_{NO}}{K_{NOH} + S_{NO}}\right] * \left[\frac{S_{NH}}{K_{NHH} + S_{NH}}\right] * \left[\frac{K_{H2SH}}{K_{H2SH} + S_{H2S^*}}\right]$$

Process 6:

$$P_{6,11} = -b_H$$

Autotrophic nitrifying bacteria

Process 7:

$$P_{7,12} = \mu_A * \left[\frac{S_{NH}}{K_{NHA} + S_{NH}}\right] * \left[\frac{S_O}{K_{OA} + S_O}\right] * \left[\frac{K_{H2SA}}{K_{H2SA} + S_{H2S^*}}\right]$$

Process 8:

$$P_{8,12} = -b_A$$

Fermenting bacteria

Process 9:

$$P_{9,13} = \mu_{FB} * \left[\frac{S_F}{K_{SFB} + S_F}\right] * \left[\frac{K_{H2SFB}}{K_{H2SFB} + S_{H2S^*}}\right] * \left[\frac{K_{OFB}}{K_{OFB} + S_O}\right] * \left[\frac{K_{NOFB}}{K_{NOFB} + S_{NO}}\right] * \left[\frac{S_{NH}}{K_{NHFB} + S_{NH}}\right]$$

Process 10:

$$P_{10,13} = -b_{FB}$$

Acetotrophic methanogenic bacteria

Process 11:

$$P_{11,14} = \mu_{AMB} * \left[\frac{S_A}{K_{SAMB} + S_A}\right] * \left[\frac{K_{H2SAMB}}{K_{H2SAMB} + S_{H2S^*}}\right] * \left[\frac{K_{OAMB}}{K_{OAMB} + S_O}\right] * \left[\frac{K_{NOAMB}}{K_{NOAMB} + S_{NO}}\right] * \left[\frac{S_{NH}}{K_{NHAMB} + S_{NH}}\right] * X_{AMB}$$

Process 12:

$$P_{12,14} = -b_{AMB}$$

Acetotrophic sulphate reducing bacteria

Process 13:

$$P_{13,15} = \mu_{ASRB} * \left[\frac{S_A}{K_{SASRB} + S_A}\right] * \left[\frac{S_{SO4}}{K_{SOASRB} + S_{SO4}}\right] * \left[\frac{K_{H2SASRB}}{K_{H2SASRB} + S_{H2S^*}}\right] * \left[\frac{K_{OASRB}}{K_{OASRB} + S_O}\right] * \left[\frac{K_{NOASRB}}{K_{NOASRB} + S_{NO}}\right] * \left[\frac{S_{NH}}{K_{NHASRB} + S_{NH}}\right]$$

Process 14:

$$P_{14,15} = -b_{ASRB}$$

Sulphide oxidising bacteria

Process 15:

$$P_{15,16} = \mu_{SOB} * \left[\frac{S_{H2S}}{K_{SSOB} + S_{H2S}}\right] * \left[\frac{S_O}{K_{OSOB} + S_O}\right] * \left[\frac{S_{NH}}{K_{NHSOB} + S_{NH}}\right]$$

Process 16:

$$P_{16,16} = \mu_{SOB} * \eta_{SOB} * \left[\frac{S_{H2S}}{K_{SSOB} + S_{H2S}}\right] * \left[\frac{S_{NO}}{K_{NOSOB} + S_{NO}}\right] * \left[\frac{K_{OSOB}}{K_{OSOB} + S_O}\right] * \left[\frac{S_{NH}}{K_{NHSOB} + S_{NH}}\right]$$

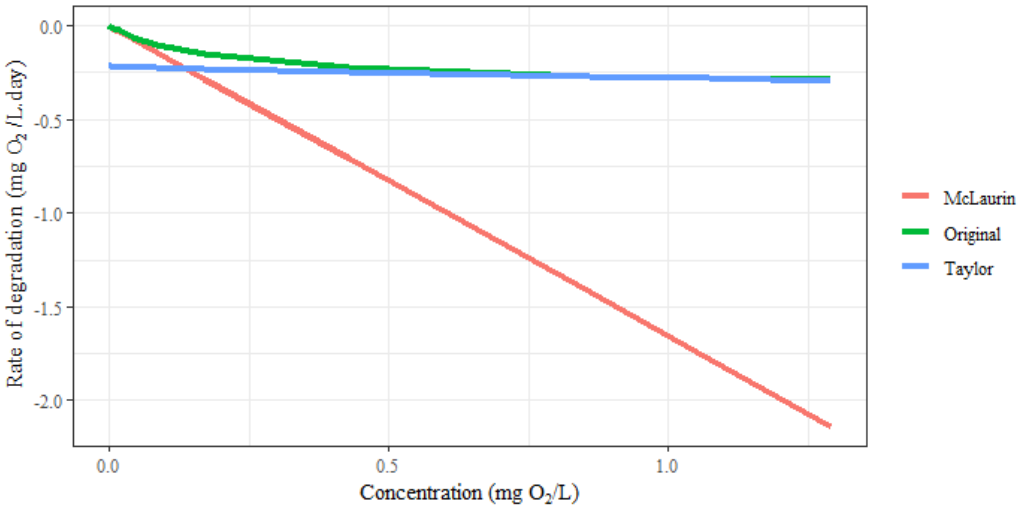

Process 14:

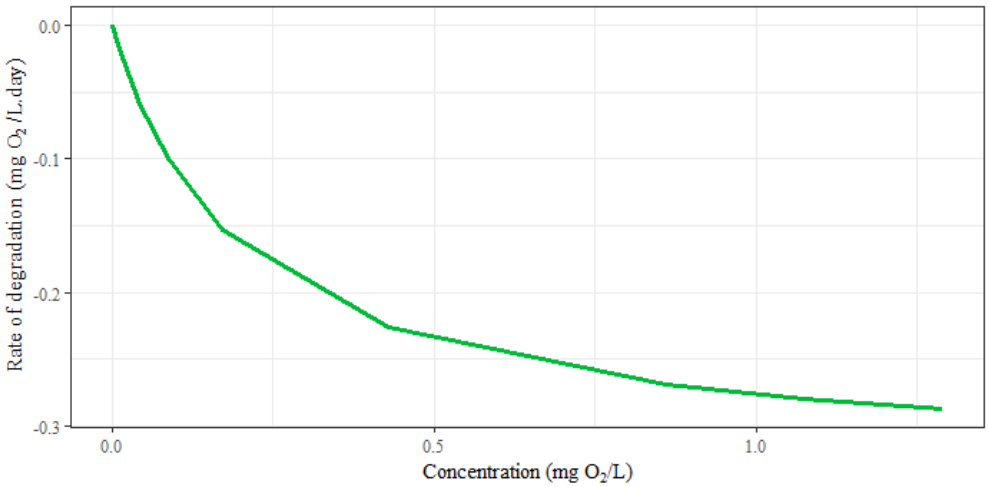

$$P_{17,16} = -b_{SOB}$$

Appendix L

The code used to run the non-linear least squares regression analysis for uranine and benzoate and generate Figure 7.7 a) , Figure 7.7 b) and Figure 7.8 a) and the hydraulic parameters presented in Section 7.3.
